2. *Effect on Elimination versus Substitution.* Strong bases not only benefit E2 as against E1, but also benefit elimination as against substitution. With a high concentration of strong base in a nonionizing solvent, bimolecular mechanisms are favored and E2 predominates over S_N2. At low base concentrations, or in the absence of base altogether, in ionizing solvents, unimolecular mechanisms are favored, and the S_N1 mechanism predominates over the

E1. In Chapter 10, it was pointed out that some species are strong nucleophiles though weak bases (p. 439). The use of these obviously favors substitution, except that, as we have seen, elimination can predominate if polar aprotic solvents are used. It has been shown for the base CN^- that in polar aprotic solvents, the less the base is encumbered by its counterion in an ion pair (i.e., the freer the base), the more substitution is favored at the expense of elimination.[110]

Effect of the Leaving Group

1. *Effect on Reactivity.* The leaving groups in elimination reactions are similar to those in nucleophilic substitution. The E2 eliminations have been performed with the following groups: NR_3^+, PR_3^+, SR_2^+, OHR^+, SO_2R, OSO_2R, OCOR, OOH OOR, NO_2,[111] F, Cl, Br, I, and CN *(not* OH_2^+. The El eliminations have been carried out with: NR_3^+, SR_2^+, OH_2^+, OHR^+, OSO_2R, OCOR, Cl, Br, I, and N_2^+.[112] However, the major leaving groups for preparative purposes are OH_2^+ (always by E1) and Cl, Br, I, and NR_3^+ (usually by E2).
2. *Effect on El versus E2 versus E1cB.* Better leaving groups shift the mechanism toward the El end of the spectrum, since they make ionization easier. This effect has been studied in various ways. One way already mentioned was a study of p values (p. 1313). Poor leaving groups and positively charged leaving groups shift the mechanism toward the E1cB end of the spectrum because the strong electron-withdrawing field effects increase the acidity of the (3 hydrogen.[113] The E2C reaction is favored by good leaving groups.
3. *Effect on Elimination versus Substitution.* As we have already seen (p. 1307), for first-order reactions the leaving group has nothing to do with the competition between elimination and substitution, since it is gone before the decision is made as to which path to take. However, where ion pairs arc involved, this is not true, and results have been found where the nature of the leaving group does affect the product.[114] In second-order reactions, the elimination/substitution ratio is not greatly dependent on a halide leaving group, though there is a slight increase in elimination in the order I > Br > Cl. When OTs is the leaving group, there is usually much more substitution. For example, *n*-$C_{18}H_{37}Br$ treated with r-BuOK gave 85% elimination, while *n*-$C_{18}H_{37}OTs$ gave, under the same conditions, 99% substitution.[115] On the other hand, positively charged leaving groups increase the amount of elimination.

Effect of the Medium

1. *Effect of Solvent on El versus E2 versus ElcB.* With any reaction a more polar environment enhances the rate of mechanisms that involve ionic intermediates. For neutral leaving groups, it is expected that El and ElcB

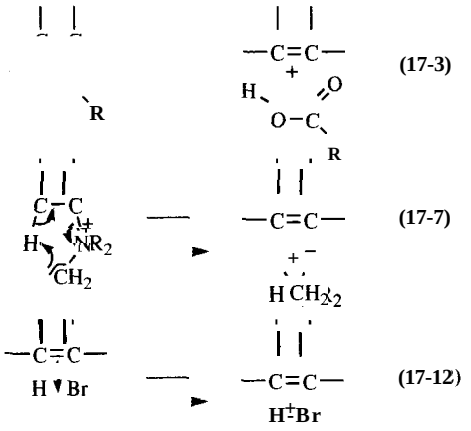
mechanisms will be aided by increasing polarity of solvent and by increasing ionic strength. With certain substrates, polar aprotic solvents promote elimination with weak bases (the E2C reaction).

2. *Effect of Solvent on Elimination versus Substitution.* Increasing polarity of solvent favors S_N2 reactions at the expense of E2. In the classical example, alcoholic KOH is used to effect elimination, while the more polar aqueous KOH is used for substitution. Charge-dispersal discussions, similar to those on page 450,[116] only partially explain this. In most solvents, S_N1 reactions are favored over E1. The El reactions compete best in polar solvents that are poor nucleophiles, especially dipolar aprotic solvents[117] A study made in the gas phase, where there is no solvent, has shown that when 1-bromopropane reacts with MeO^- only elimination takes place no substitution even with this primary substrate.[118]
3. *Effect of Temperature.* Elimination is favored over substitution by increasing temperature, whether the mechanism is first or second order.[119] The reason is that the activation energies of eliminations are higher than those of substitutions (because eliminations have greater changes in bonding).

MECHANISMS AND ORIENTATION IN PYROLYTIC ELIMINATIONS

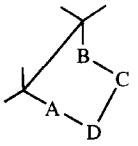
Mechanisms[120]

Several types of compound undergo elimination on heating, with no other reagent present. Reactions of this type are often run in the gas phase. The mechanisms are obviously different from those already discussed, since all those require a base (which may be the solvent) in one of the steps, and there is no base or solvent present in pyrolytic elimination. Two mechanisms have been found to operate. One involves a cyclic transition state, which may be four, five, or six membered. Examples of each size are



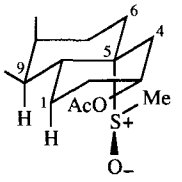
In this mechanism, the two groups leave at about the same time and bond to each other as they are doing so. The designation is Ei in the Ingold terminology and *cyclo-*

$D_ED_NA_n$ in the IUPAC system. The elimination must be syn and, for the four- and five-membered transition states, the four or five atoms making up the ring must be coplanar. Coplanarity is not required for the six-membered transition state, since there is room for the outside atoms when the leaving atoms are staggered.

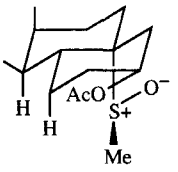


As in the E2 mechanism, it is not necessary that the C—H and C—X bond be equally broken in the transition state. In fact, there is also a spectrum of mechanisms here, ranging from a mechanism in which C—X bond breaking is a good deal more advanced than C—H bond breaking to one in which the extent of bond breaking is virtually identical for the two bonds. Evidence for the existence of the Ei mechanism is

1. The kinetics are first order, so only one molecule of the substrate is involved in the reaction (that is, if one molecule attacked another, the kinetics would be second order in substrate).[121]
2. Free-radical inhibitors do not slow the reactions, so no free-radical mechanism is involved.[122]
3. The mechanism predicts exclusive syn elimination, and this behavior has been found in many cases.[123] The evidence is inverse to that for the anti E2 mechanism and generally involves the following facts: (1) an erythro isomer gives a trans alkene and a threo isomer gives a cis alkene; (2) the reaction takes place only when a cis β hydrogen is available; (3) if, in a cyclic compound, a cis hydrogen is available on only one side, the elimination goes in that direction. Another piece of evidence involves a pair of steroid molecules. In 3β-acetoxy-(*R*)-5α-methylsulfinylcholestane (26 shows rings A and B of this compound) and in 3β -acetoxy-(*S*)-5α-methylsulfinylcholestane (27: rings A and B), the *only* difference is the configuration of oxygen and methyl



26



27

about the sulfur. Yet pyrolysis of 26 gave only elimination to the 4-side (86% 4-ene), while 27 gave predominant elimination to the 6-side (65% 5-ene and 20% 4-ene).[124] Models show that interference from the 1- and 9-hydrogens causes the two groups on the sulfur to lie *in front of it* with respect to the rings, rather than behind it. Since the sulfur is chiral, this means that in 26 the oxygen is near the 4 hydrogen, while in 27 it is near the 6 hydrogen. This experiment is compatible only with syn elimination.[125]

4. The ^{14}C isotope effects for the Cope elimination **(17-8)** show that both the C—H and C—N bonds have been extensively broken in the transition state.[126]
5. Some of these reactions have been shown to exhibit negative entropies of activation, indicating that the molecules are more restricted in geometry in the transition state than they are in the starting compound.

Where a pyrolytic elimination lies on the mechanistic spectrum seems to depend mostly on the leaving group. When this is halogen, all available evidence suggests that in the transition state the C—X bond is cleaved to a much greater extent than the C—H bond, that is, there is a considerable amount of carbocation character in the transition state. This is in accord with the fact that a completely nonpolar four-membered cyclic transition state violates the Woodward-Hoffmann rules (see the similar case of **15-61).** Evidence for the carbocation-like character of the transition state when halide is the leaving group is that relative rates are in the order I > Br > Cl[127] (see p. 445), and that the effects of substituents on reaction rates are in accord with such a transition state.[128] Rate ratios for pyrolysis of some alkyl bromides at 320°C were: ethyl bromide, 1; isopropyl bromide, 280; *tert*-butyl bromide, 78,000. Also, α-phenylethyl bromide had about the same rate as terf-butyl bromide. On the other hand, β-phenylethyl bromide was only slightly faster than ethyl bromide.[129] This indicates that C—Br cleavage was much more important in the transition state than C—H cleavage, since the incipient carbocation was stabilized by a alkyl- and α-aryl substitution, while there was no incipient carbanion to be stabilized by β-aryl substitution. These substituent effects, as well as those for other groups, are very similar to the effects found for the S_N1 mechanism and thus in very good accord with a carbocation-like transition state.

For carboxylic esters, the rate ratios were much smaller,[130] though still in the same order, so that this reaction is closer to a pure Ei mechanism, though the transition state still has some carbocationic character. Other evidence for a greater initial C—O cleavage with carboxylic esters is that a series of 1-arylethyl acetates followed σ^+ rather than a, showing carbocationic character at the 1 position.[131] The extent of El character in the transition state increases in the following order of ester types: acetate < phenylacetate < benzoate < carbamate < carbonate.[132] Cleavage of xanthates (17-4), cleavage of sulfoxides **(17-11),** the Cope reaction (17-8), and Reaction **17-7** are probably very close to straight Ei mechanisms.[133]

The second type of pyrolysis mechanism is completely different and involves free radicals. Initiation occurs by pyrolytic homolytic cleavage. The remaining steps may vary, and a few are shown

Initiation

$$R_2CHCH_2X \longrightarrow R_2CHCH_2\cdot + X\cdot$$

Propagation

$$R_2CHCH_2X + X\cdot \longrightarrow R_2\dot{C}CH_2X + HX$$

$$R_2\dot{C}CH_2X \longrightarrow CH_2{=}CH_2 + X\cdot$$

Termination (disproportionation)

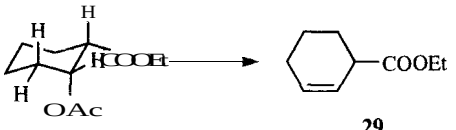
$$2\,R_2\dot{C}CH_2X \longrightarrow R_2C{=}CH_2 + R_2CXCH_2X$$

Free-radical mechanisms are mostly found in pyrolyses of polyhalides and of primary monohalides,[134] though they also have been postulated in pyrolysis of certain carboxylic esters.[135] Much less is known about these mechanisms and we shall not consider them further. Free-radical eliminations in solution are also known but are rare.[136]

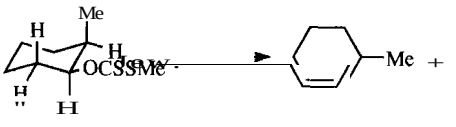
Orientation in Pyrolytic Eliminations

As in the El-E2-E1cB mechanistic spectrum, Bredt's rule applies; and if a double bond is present, a conjugated system will be preferred, if sterically possible. Apart from these considerations, the following statements can be made for Ei eliminations:

1. In the absence of considerations mentioned below, orientation is statistical and is determined by the number of β hydrogens available (therefore *Hofmann's rule* is followed). For example, sec-butyl acetate gives 55-62% 1-butene and 38-45% 2-butene,[137] which is close to the 3:2 distribution predicted by the number of hydrogens available.[138]
2. A cis β hydrogen is required. Therefore in cyclic systems, if there is a cis hydrogen on only one side, the double bond will go that way. However, when there is a six-membered transition state, this does not necessarily mean that the leaving groups must be cis to each other, since such transition states need not be completely coplanar. If the leaving group is axial, then the hydrogen obviously must be equatorial (and consequently cis to the leaving group), since the transition state cannot be realized when the groups are both axial. But if the leaving group is equatorial, it can form a transition state with a β hydrogen that is either axial (hence, cis) or equatorial (hence, trans). Thus 28, in which the leaving group is most likely axial, does not form a double bond



28 **29** (17-3)



30 (17-4)

in the direction of the carbethoxyl group, even though that would be conjugated, because there is no equatorial hydrogen on that side. Instead it gives 100% **29**.[139] On the other hand, 30, with an equatorial leaving group, gives ~50% of each alkene, even though, for elimination to the 1-ene, the leaving group must go off with a trans hydrogen.[140]
3. In some cases, especially with cyclic compounds, the more stable alkene forms and Zaitsev's rule applies. For example, menthyl acetate gives 35% of

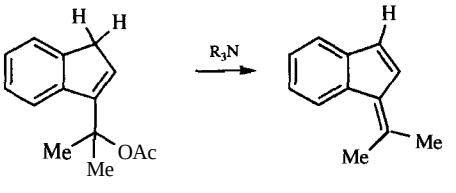
the Hofmann product and 65% of the Zaitsev, even though a cis β hydrogen is present on both sides and the statistical distribution is the other way. A similar result was found for the pyrolysis of menthyl chloride.[141]

4. There are also steric effects. In some cases the direction of elimination is determined by the need to minimize steric interactions in the transition state or to relieve steric interactions in the ground state.

1,4 Conjugate Eliminations[142]

1,4 Eliminations of the type

are much rarer than conjugate additions (Chapter 15), but some examples are known.[143] One such is[144]



REACTIONS

First, we consider reactions in which a C=C or a C≡C bond is formed. From a synthetic point of view, the most important reactions for the formation of double bonds are 17-1 (usually by an El mechanism), **17-6**, **17-12**, and 17-22 (usually by an E2 mechanism), and 17-3, 17-4, and 17-8 (usually by an Ei mechanism). The only synthetically important method for the formation of triple bonds is **17-12**.[145] In the second section, we treat reactions in which C≡N bonds and C=N bonds are formed, and then eliminations that give C=O bonds and diazoalkanes. Finally, we discuss extrusion reactions.

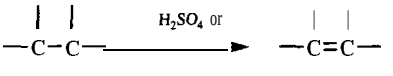
Reactions in Which C=C and C≡C Bonds Are Formed

A. *Reactions in Which Hydrogen Is Removed from One Side*

In 17-1-17-5, the other leaving atom is oxygen. In 17-6-17-10, it is nitrogen. For reactions in which hydrogen is removed from both sides, see 19-1-19-6.

17-1 *Dehydration of Alcohols*

HYDRO-HYDROXY-ELIMINATION



Dehydration of alcohols can be accomplished in several ways. Both H_2SO_4 and H_3PO_4 are common reagents, but in many cases these lead to rearrangement products and to ether formation **(10-16).** If the alcohol can be evaporated, vapor-phase elimination over Al_2O_3 is an excellent method since side reactions are greatly reduced. This method has even been applied to such high molecular weight alcohols as 1-dodecanol.[146] Other metallic oxides (e.g., Cr_2O_3, TiO_2, WO_3) have also been used, as have been sulfides, other metallic salts, and zeolites. The presence of an electron withdrawing group usually facilitates elimination of water, as in the aldol condensation **(16-39).** 2-Nitroalcohols, for example, give conjugated nitro compounds when heated with zeolite Y–Y.[147] Treating a 4-hydroxy lactam with DMAP (*N*,*N*-dimethylaminopyridine) and *t*-Boc anhydride leads to the conjugated lactam.[148] Elimination of serine derivatives to α-alkylidene amino acid derivatives was accomplished with $(EtO)_2POCl$.[149] Another method of avoiding side reactions is the conversion of alcohols to esters, and the pyrolysis of these **(17-3-17-5).** The ease of dehydration increases with α branching, and tertiary alcohols are dehydrated so easily with only a trace of acid that it sometimes happens even when the investigator desires otherwise. It may also be recalled that the initial alcohol products of many base-catalyzed condensations dehydrate spontaneously (Chapter 16) because the new double bond can be in conjugation with one already there. Many other dehydrating agents[150] have been used on occasion: P_2O_5, I_2, $ZnCl_2$, Ph_3BiBr_2/I_2,[151] BF_3–etherate, DMSO, $KHSO_4$, anhydrous $CuSO_4$, and phthalic anhydride, among others. Secondary and tertiary alcohols can also be dehydrated, without rearrangements, simply on refluxing in HMPA.[152] With nearly all reagents, dehydration follows Zaitsev's rule. An exception involves the passage of hot alcohol vapors over thorium oxide at 350-450°C, under which conditions Hofmann's rule is followed,[153] and the mechanism is probably different.

Carboxylic acids can be dehydrated by pyrolysis, the product being a ketene:

$$\mathrm{R{-}\underset{\displaystyle H}{\underset{|}{CH}}{-}\underset{\displaystyle OH}{\underset{|}{C}}{=}O} \xrightarrow{\Delta} \mathrm{R\text{-}CH{=}C{=}O}$$

Ketene itself is commercially prepared in this manner. Carboxylic acids have also been converted to ketenes by treatment with certain reagents, among them TsCl,[154] DCC,[155] and 1-methyl-2-chloropyridinium iodide *{Mukaiyama's reagent)}*[56] Analogously, amides can be dehydrated with P_2O_5, pyridine, and Al_2O_3 to give ketenimines:[157]

$$\mathrm{R_2CH{-}\underset{\displaystyle O}{\underset{\|}{C}}{-}NHR' \xrightarrow[\text{pyridine}]{P_2O_5,\ Al_2O_3} R_2C{=}C{=}NR'}$$

There is no way in which dehydration of alcohols can be used to prepare triple bonds: *gem*-diols and vinylic alcohols are not normally stable compounds and *vic*-diols[158] give either conjugated dienes or lose only 1 mol of water to give an aldehyde or ketone. Dienes can be prepared, however, by heating alkynyl alcohols with triphenyl phosphine.[159]

When proton acids catalyze alcohol dehydration, the mechanism is E1.[160] The principal process involves conversion of ROH to ROH_2^+ and cleavage of the latter to R^+ and H_2O, though with some acids a secondary process probably involves conversion of the alcohol to an inorganic ester and ionization of *this* (illustrated for H_2SO_4):

$$ROH \xrightarrow{H_2SO_4} ROSO_2OH \longrightarrow R^+ + HSO_4^-$$

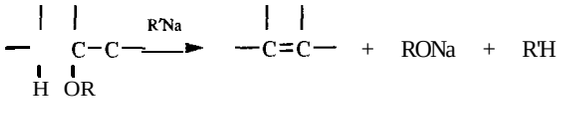
Note that these mechanisms are the reverse of those involved in the acid-catalyzed hydration of double bonds (15-3), in accord with the principle of microscopic reversibility. With anhydrides (e.g., P_2O_5, phthalic anhydride) as well as with some other reagents such as HMPA,[161] it is likely that an ester is formed, and the leaving group is the conjugate base of the corresponding acid. In these cases, the mechanism can be E1 or E2. The mechanism with Al_2O_3 and other solid catalysts has been studied extensively but is poorly understood.[162]

Magnesium alkoxides (formed by $ROH + Me_2Mg \rightarrow ROMgMe$) have been decomposed thermally, by heating at 195–340°C to give the alkene, CH_4, and MgO.[163] Syn elimination is found and an Ei mechanism is likely. Similar decomposition of aluminum and zinc alkoxides has also been accomplished.[164]

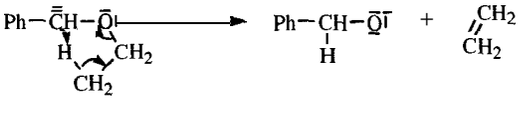
OS **I,** 15, 183, 226, 280, 345, 430, 473, 475; **II,** 12, 368, 408, 606; **III,** 22, 204, 237, 312, 313, 353, 560, 729, 786; **IV,** 130, 444, 771; **V,** 294; **VI,** 307, 901; **VII,** 210, 241, 363, 368, 396; **VIII,** 210, 444. See also OS **VII,** 63; **VIII,** 306, 474. No attempt has been made to list alkene-forming dehydrations accompanying condensations or rearrangements.

17-2 *Cleavage of Ethers to Alkenes*

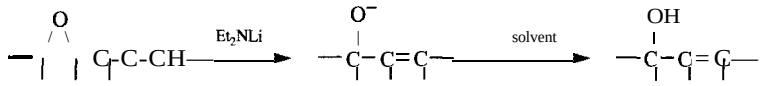
HYDRO-ALKOXY-ELIMINATION



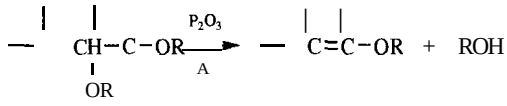
Alkenes can be formed by the treatment of ethers with very strong bases, such as alkylsodium or alkyllithium compounds or sodium amide,[165] though there are usually side reactions too. The reaction is aided by electron-withdrawing groups in the β position, and, for example, $EtOCH_2CH(COOEt)_2$ can be converted to $CH_2=C(COOEt)_2$ without any base at all, but simply on heating.[166] ter?-Butyl ethers are cleaved more easily than others. Several mechanisms are possible. In many cases the mechanism is probably E1cB or on the E1cB side of the mechanistic spectrum,[167] since the base required is so strong, but it has been shown (by the use of $PhCD_2OEt$) that $PhCH_2OEt$ reacts by the five-membered Ei mechanism:[168]



Epoxides can be converted to allylic alcohols[169] by treatment with several reagents, including *sec*-butyllithium,[170] *tert*-butyldimethylsilyl iodide,[171] and *i*-Pr_2NLi-*t*-BuOK (the *LIDAKOR reagent)*.[172] When an optically active reagent is used, optically active allylic alcohols can be produced from achiral epoxides.[173]

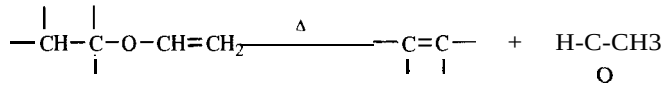


Ethers have also been converted to alkenes and alcohols by passing vapors over hot P_2O_5 or Al_2O_3 (this method is similar to **17-1),** but this is not a general reaction. Cyclic ethers such as THF react slowly with organolithium reagents with cleavage that produces a C=C unit.[174] Fragmentation of 2,5-dihydrofuran with ethylmagnesium chloride and a chiral zirconium catalyst leads to a chiral, homoallylic alcohol.[175] However, acetals can be converted to enol ethers in this manner:



This can also be done at room temperature by treatment with trimethylsilyl triflate and a tertiary amine[176] or with Me_3SiI in the presence of hexamethyldisilazane.[177]

Enol ethers can be pyrolyzed to alkenes and aldehydes in a manner similar to that of 17-3:

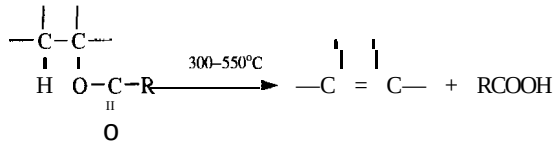


The rate of this reaction for $R-O-CH=CH_2$ increased in the order Et < *i*-Pr < *t*-Bu.[178] The mechanism is similar to that of 17-3.

OS **IV,** 298, 404; V, 25, 642, 859, 1145; **VI,** 491, 564, 584, 606, 683, 948; **VIII,** 444.

17-3 *Pyrolysis of Carboxyllc Acids and Esters of Carboxylic Acids*

HYDRO-ACYLOXY-ELIMINATION



Direct elimination of a carboxylic acid to an alkene has been accomplished by heating in the presence of palladium catalysts.[179] Carboxylic esters in which the alkyl group has a β hydrogen can be pyrolyzed, most often in the gas phase, to give the corresponding acid and an alkene.[180] No solvent is required. Since rearrangement and other side reactions are few, the reaction is synthetically very useful and is often carried out as an indirect method of accomplishing **17-1.** The yields are excellent and the work up is easy. Many alkenes have been prepared in this manner.

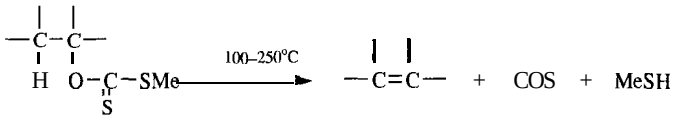
For higher alkenes (above ~C_{10}) a better method is to pyrolyze the alcohol in the presence of acetic anhydride.[181]

The mechanism is Ei (see p. 1322). Lactones can be pyrolyzed to give unsaturated acids, provided that the six-membered transition state required for Ei reactions is available (it is not available for five- and six-membered lactones, but it is for larger rings[182]). Amides give a similar reaction but require higher temperatures.

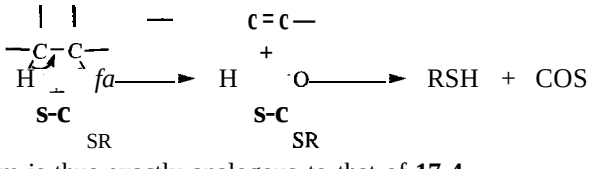
Allylic acetates give dienes when heated with certain palladium[183] or molybdenum[184] compounds.

OS **III,** 30; IV, 746; V, 235; IX, 293.

17-4 *The Chugaev Reaction*



Methyl xanthates are prepared by treatment of alcohols with NaOH and CS_2 to give RO—CS—SNa, followed by treatment of this with methyl iodide.[185] Pyrolysis of the xanthate to give the alkene, COS, and the thiol is called the *Chugaev reaction.*[186] The reaction is thus, like 17-3, an indirect method of accomplishing 17-2. The temperatures required with xanthates are lower than with ordinary esters, which is advantageous because possible isomerization of the resulting alkene is minimized. The mechanism is Ei, similar to that of 17-3. For a time there was doubt as to which sulfur atom closed the ring, but now there is much evidence, including the study of ^{34}S and ^{13}C isotope effects, to show that it is the C=S sulfur:[187]

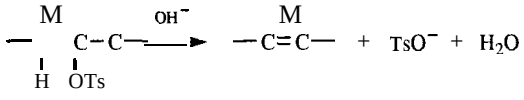


The mechanism is thus exactly analogous to that of **17-4.**

OS **VII,** 139.

17-5 *Decomposition of Other Esters*

HYDRO-TOSYLOXY-ELIMINATION



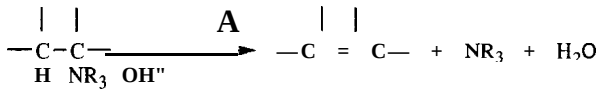
Several types of inorganic ester can be cleaved to alkenes by treatment with bases. Esters of sulfuric, sulfurous, and other acids undergo elimination in solution by E1 or E2 mechanisms, as do tosylates and other esters of sulfonic acids.[188] It has been shown that bis(tetra-*n*-butylammonium) oxalate, $(Bu_4N^+)_2$ $(COO^-)_2$, is an

excellent reagent for inducing tosylates to undergo elimination rather than substitution.[189] Aryl sulfonates have also been cleaved without a base. Esters of 2-pyridinesulfonic acid and 8-quinolinesulfonic acid gave alkenes in high yields simply on heating, without a solvent.[190] Phosphonate esters have been cleaved to alkenes by treatment with Lawesson's reagent.[191] Esters of $PhSO_2OH$ and TsOH behaved similarly when heated in a dipolar aprotic solvent such as Me_2SO or HMPA.[192]

OS, VI, 837; **VII,** 117.

17-6 *Cleavage of Quaternary Ammonium Hydroxides*

HYDRO-TRIALKYLAMMONIO-ELIMINATION

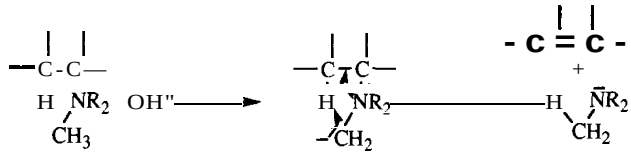


Cleavage of quaternary ammonium hydroxides is the final step of the process known as *Hofmann exhaustive methylation or Hofmann degradation*.[193] In the first step, a primary, secondary, or tertiary amine is treated with enough methyl iodide to convert it to the quaternary ammonium iodide **(10-44).** In the second step, the iodide is converted to the hydroxide by treatment with silver oxide. In the cleavage step, an aqueous or alcoholic solution of the hydroxide is distilled, often under reduced pressure. The decomposition generally takes place at a temperature between 100 and 200°C. Alternatively, the solution can be concentrated to a syrup by distillation or freeze-drying.[194] When the syrup is heated at low pressures, the cleavage reaction takes place at lower temperatures than are required for the reaction in the ordinary solution, probably because the base (OH^- or RO^-) is less solvated.[195] The reaction has never been an important synthetic tool, but in the nineteenth century and the first part of the twentieth century it saw much use in the determination of the structure of unknown amines, especially alkaloids. In many of these compounds the nitrogen is in a ring, or even at a ring junction, and in such cases the alkene still contains nitrogen. Repetitions of the process are required to remove the nitrogen completely, as in the conversion of 2-methylpiperidine to 1,5-hexadiene by two rounds of exhaustive methylation followed by pyrolysis.

A side reaction involving nucleophilic substitution to give an alcohol ($R_4N^+ \ OH^- \rightarrow ROH + R3N$) generally accompanies the normal elimination reaction[196] but seldom causes trouble. However, when none of the four groups on the nitrogen has a β hydrogen, substitution is the only reaction possible. On heating $Me_4N^+OH^-$ in water, methanol is obtained, though without a solvent the product is not methanol but dimethyl ether.[197]

The mechanism is usually E2. Hofmann's rule is generally obeyed by acyclic and Zaitsev's rule by cyclohexyl substrates (p. 1315). In certain cases, where the molecule is highly hindered, a five-membered Ei mechanism, similar to that in **17-7,** has been shown to operate. That is, the OH^- in these cases does not attract the β

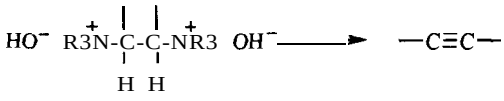
hydrogen, but instead removes one of the methyl hydrogens:



The obvious way to distinguish between this mechanism and the ordinary E2 mechanism is by the use of deuterium labeling. For example, if the reaction is carried out on a quaternary hydroxide deuterated on the (3 carbon ($R_2CDCH_2NMe_3^+$ OH^-), the fate of the deuterium indicates the mechanism. If the E2 mechanism is in operation, the trimethylamine produced would contain no deuterium (which would be found only in the water). But if the mechanism is Ei, the amine would contain deuterium. In the case of the highly hindered compound $(Me_3C)_2CDCH_2NMe_3^+$ OH^-, the deuterium did appear in the amine, demonstrating an Ei mechanism for this case.[198] With simpler compounds, the mechanism is E2, since here the amine was deuterium-free.[199]

When the nitrogen bears more than one group possessing a (3 hydrogen, which group cleaves? The Hofmann's rule says that *within* a group the hydrogen is on the least alkylated carbon cleaves. This tendency is also carried over to the choice of which group cleaves: thus ethyl with three β hydrogens cleaves more readily than any longer *n*-alkyl group, all of which have two β hydrogens. "The β hydrogen is removed most readily if it is located on a methyl group, next from RCH_2, and least readily from R_2CH."[200] In fact, the Hofmann's rule as first stated[201] in 1851 applied only to which group cleaved, not to the orientation within a group; the latter could not have been specified in 1851, since the structural theory of organic compounds was not formulated until 1857–1860. Of course, the Hofmann rule (applied to which group cleaves *or* to orientation within a group) is superseded by conjugation possibilities. Thus $PhCH_2CH_2NMe_2Et^+OH^-$ gives mostly styrene instead of ethylene.

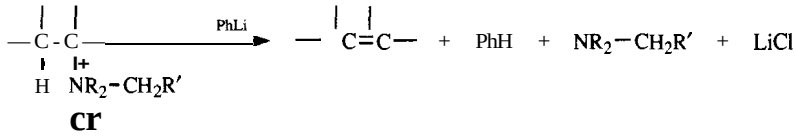
Triple bonds have been prepared by pyrolysis of 1,2-bis salts.[202]



OS IV, 980; V, 315, 608; VI, 552. Also see OS V, 621, 883; VI, 75.

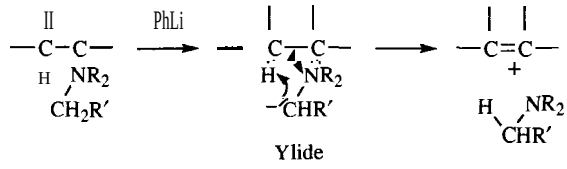
17-7 *Cleavage of Quaternary Ammonium Salts With Strong Bases*

HYDRO-TRIALKYLAMMONIO-ELIMINATION



cr

When quaternary ammonium halides are treated with strong bases (e.g., PhLi, KNH_2 in liquid NH3[203]), an elimination can occur that is similar in products, though not in mechanism, to **17-6.** This is an alternative to **17-6** and is done on the quaternary ammonium halide, so that it is not necessary to convert this to the hydroxide. The mechanism is Ei:

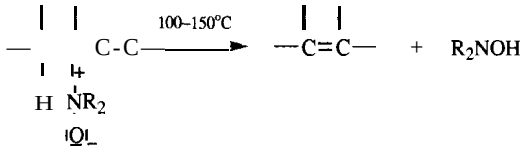


An α' hydrogen is obviously necessary in order for the ylide to be formed. This type of mechanism is called a',(3 elimination, since a (3 hydrogen is removed by the α' carbon. The mechanism has been confirmed by labeling experiments similar to those described at 17-6,[204] and by isolation of the intermediate ylids.[205] An important synthetic difference between this and most instances of **17-6** is that syn elimination is observed here and anti elimination in **17-6,** so products of opposite configuration are formed when the alkene exhibits cis-trans isomerism.

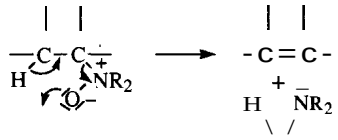
An alternative procedure that avoids the use of a very strong base is heating the salt with KOH in polyethylene glycol monomethyl ether.[206]

17-8 *Cleavage of Amine Oxides*

HYDRO-(DIALKYLOXIDOAMMONIO)-ELIMINATION



Cleavage of amine oxides to produce an alkene and a hydroxylamine is called the *Cope reaction* or *Cope elimination* (not to be confused with the Cope *rearrangement,* **18-32).** It is an alternative to **17-6** and **17-7**.[207] The reaction is usually performed with a mixture of amine and oxidizing agent (see **19-27)** without isolation of the amine oxide. Because of the mild conditions side reactions are few, and the alkenes do not usually rearrange. The reaction is thus very useful for the preparation of many alkenes. A limitation is that it does not open 6-membered rings containing nitrogen, though it does open rings of 5 and 7-10 members.[208] Rates of the reaction increase with increasing size of a and (3 substituents.[209] The reaction can be carried out at room temperature in dry Me_2SO or THE[210] The elimination is a stereoselective syn process,[211] and the five-membered Ei mechanism operates:

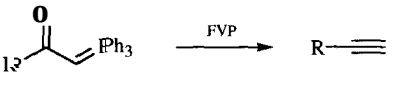


Almost all evidence indicates that the transition state must be planar. Deviations from planarity as in 17-3 (see p. 1322) are not found here, and indeed this is why six-membered heterocyclic nitrogen compounds do not react. Because of the stereoselectivity of this reaction and the lack of rearrangement of the products, it is useful for the formation of trans cycloalkenes (eight-membered and higher).

OS IV, 612.

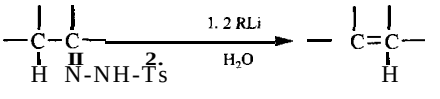
17-9 *Pyrolysis of Keto-ylids*

HYDRO-(OXOPHOSPHORYL)-ELIMINATION

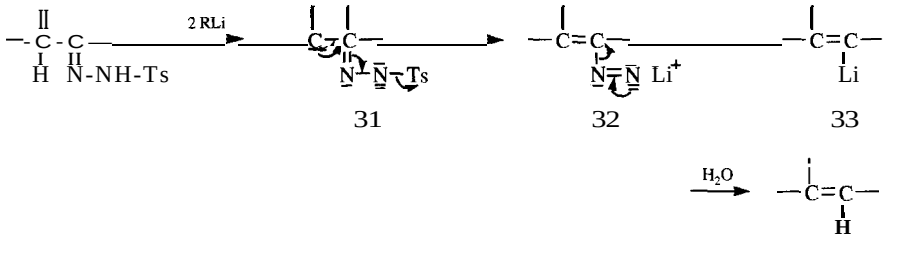


Phosphorus ylids are quite common (see **16-47)** and keto-phosphorus ylids (RCOCH=PPh3) are also known. When these compounds are heating (flash vacuum pyrolysis, FVP) to great than >500°C, alkynes are formed. Simple alkynes[212] can be formed as well as keto-alkynes[213] and en-ynes.[214]

17-10 *Decomposition of Toluene-p-sulfonylhydrazones*



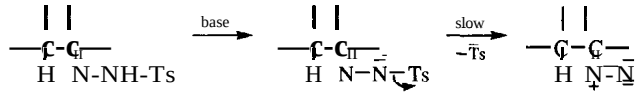
Treatment of the tosylhydrazone of an aldehyde or a ketone with a strong base leads to the formation of an alkene, the reaction being formally an elimination accompanied by a hydrogen shift.[215] The reaction (called the *Shapiro reaction)* has been applied to tosylhydrazones of many aldehydes and ketones. The most useful method synthetically involves treatment of the substrate with at least two equivalents of an organolithium compound[216] (usually MeLi) in ether, hexane, or tetramethylenediamine.[217] This procedure gives good yields of alkenes without side reactions and, where a choice is possible, predominantly gives the less highly substituted alkene. Tosylhydrazones of α,β-unsaturated ketones give conjugated dienes.[218] The mechanism[219] has been formulated as:



Evidence for this mechanism is (1) two equivalents of RLi are required; (2) the hydrogen in the product comes from the water and not from the adjacent carbon, as

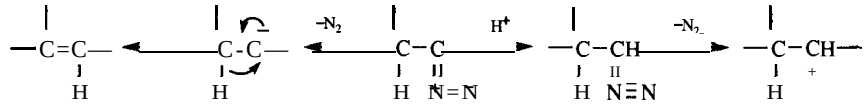
shown by deuterium labeling;[220] and (3) the intermediates 31-33 have been trapped.[221] This reaction, when performed in tetramethylenediamine, can be a synthetically useful method[222] of generating vinylic lithium compounds (33), which can be trapped by various electrophiles[223] such as D_2O (to give deuterated alkenes), CO2 (to give α,β-unsaturated carboxylic acids—**16-34**), or DMF (to give α,β-unsaturated aldehydes—**10-115**). Treatment of N-aziridino hydrazones with LDA leads to alkenes with high cis selectivity.[224]

The reaction also takes place with other bases (e.g., LiH,[225] Na in ethylene glycol, NaH, $NaNH_2$) or with smaller amounts of RLi, but in these cases side reactions are common and the orientation of the double bond is in the other direction (to give the more highly substituted alkene). The reaction with Na in ethylene glycol is called the *Bamford–Stevens reaction.*[226] For these reactions two mechanisms are possible—a carbenoid and a carbocation mechanism.[227] The side reactions found are those expected of carbenes and carbocations. In general, the carbocation mechanism is chiefly found in protic solvents and the carbenoid mechanism in aprotic solvents. Both routes involve formation of a diazo compound (34) which in some cases can be isolated.



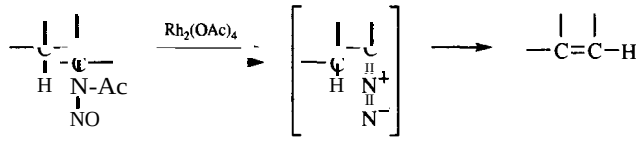
34

In fact, this reaction has been used as a synthetic method for the preparation of diazo compounds.[228] In the absence of protic solvents 34 loses N_2, and hydrogen migrates, to give the alkene product. The migration of hydrogen may immediately follow, or



34 35

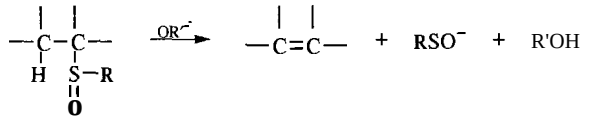
be simultaneous with, the loss of N_2. In a protic solvent, 34 becomes protonated to give the diazonium ion 35, which loses N_2 to give the corresponding carbocation that may then undergo elimination or give other reactions characteristic of carbocations. A diazo compound is an intermediate in the formation of alkenes by treatment of N-nitrosoamides with a rhodium(II) catalyst.[229]



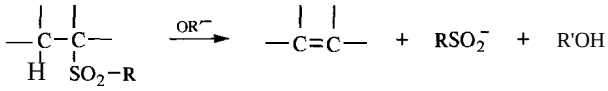
OS VI, 172; VII, 77; IX, 147. For the preparation of a diazo compound, see OS VII, 438.

17-11 *Cleavage of Sulfoxides, Selenoxides, and Sulfones*

Hydro-alkylsulfinyl-elimination



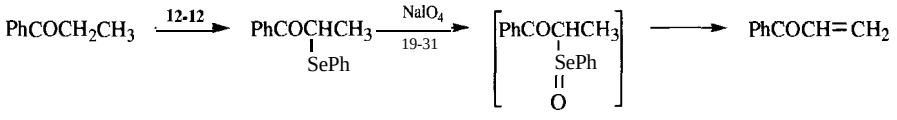
Hydro-alkylsulfinyl-elimination



Sulfonium compounds ($-C-{}^{+}SR_2$) undergo elimination similar to that of their ammonium counterparts **(17-6** and **17-7)** in scope and mechanism but this reaction is not of great synthetic importance. These **syn-elimination** reactions are related to the Cope elimination **(17-8)** and the Hofmann elimination (**17-6**).[230]

Sulfones and sulfoxides with a β hydrogen, on the other hand, undergo elimination on treatment with an alkoxide or, for **sulfones,**[231] even with OH^-.[232] Sulfones also eliminate in the presence of an organolithium reagent and a palladium catalyst.[233] In mechanism, these reactions belong on the El-E2-ElcB spectrum.[234] Although the leaving groups are uncharged, the orientation follows Hofmann's rule, not Zaitsev's. Sulfoxides (but not sulfones) also undergo elimination on pyrolysis at ~80°C in a manner analogous to **17-8.** The mechanism is also analogous, being the five-membered-Ei mechanism with syn elimination.[235] Selenoxides[236] and **sulfinate** esters $R_2CH-CHR-SO-OMe$[237] also undergo elimination by the Ei mechanism, the selenoxide reaction taking place at room temperature. The reaction with selenoxides has been extended to the formation of triple bonds.[238]

Both the selenoxide[239] and sulfoxide[240] reactions have been used in a method for the conversion of ketones, aldehydes, and carboxylic esters to their α,β-unsaturated derivatives (illustrated for the selenoxide).



Because of the mildness of the procedure, this is probably the best means of accomplishing this conversion. See page 555 for another application of the selenoxide reaction. Allylic sulfoxides undergo 1,4 elimination to give **dienes.**[241]

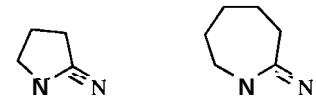
OS **VI,** 23, 737; **VIII,** 543; **IX,** 63.

17-12 *Dehydrohalogenation of Alkyl Halides*

HYDRO-HALO-ELIMINATION

The elimination of HX from an alkyl halide is a very general reaction and can be accomplished with chlorides, fluorides, bromides, and iodides.[242] Hot alcoholic

KOH is the most frequently used base, though stronger bases (OR^-, NH_2^-, etc.)[243] or weaker ones (e.g., amines) are used where warranted.[244] The bicyclic amidines 1,5-diazabicyclo[3.4.0]non-5-ene (DBN)[245] and DBU[246] are good reagents

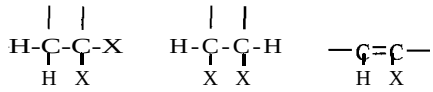


DBN DBU

for difficult cases.[247] Dehydrohalogenation with the non-ionic base $(Me_2N)_3P{=}N{-}P(NMe_2)_2{=}NMe$ is even faster.[248] Phase-transfer catalysis has been used with OH^- as base.[249] As previously mentioned (p. 1313), certain weak bases in dipolar aprotic solvents are effective reagents for dehydrohalogenation. Among those most often used for synthetic purposes are LiCl or $LiBr{-}LiCO_3$ in DMF.[250] Dehydrohalogenation has also been effected by heating of the alkyl halide in HMPA with no other reagent present.[251] As in nucleophilic substitution (p. 445), the order of leaving group reactivity is I > Br > Cl > F.[252]

Tertiary halides undergo elimination most easily. Eliminations of chlorides, bromides, and iodides follow Zaitsev's rule, except for a few cases where steric effects are important (for an example, see p. 1316). Eliminations of fluorides follow Hofmann's rule (p. 1316).

This reaction is by far the most important way of introducing a triple bond into a molecule.[253] This can be accomplished with substrates of the types:[254]



When the base is $NaNH_2$ 1-alkynes predominate (where possible), because this base is strong enough to form the salt of the alkyne, shifting any equilibrium between 1- and 2-alkynes. When the base is OH^- or OR", the equilibrium tends to be shifted to the internal alkyne, which is thermodynamically more stable. If another hydrogen is suitably located (e.g., $-CRH{-}CX_2{-}CH_2-$), allene formation can compete, though alkynes are usually more stable.

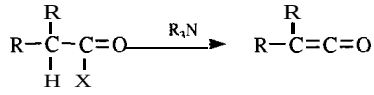
Dehydrohalogenation is generally carried out in solution, with a base, and the mechanism is usually E2, though the El mechanism has been demonstrated in some cases. However, elimination of HX can be accomplished by pyrolysis of the halide, in which case the mechanism is Ei (p. 1322) or, in some instances, the free-radical mechanism (p. 1324). Pyrolysis is normally performed without a catalyst at ~400°C. The pyrolysis reaction is not generally useful synthetically, because of its reversibility. Less work has been done on pyrolysis with a catalyst[255] (usually a metallic oxide or salt), but the mechanisms here are probably El or E2.

In the special case of the prochiral carboxylic acids (36), dehydrohalogenation with an optically active lithium amide gave an optically active product with enantiomeric excesses as high as 82%.[256]

OS I, 191, 205, 209, 438; II, 10, 17, 515; **III,** 125, 209, 270, 350, 506, 623, 731, 785; IV, 128, 162, 398, 404, 555, 608, 616, 683, 711, 727, 748, 755, 763, 851, 969; V, 285, 467, 514; VI, 87, 210, 327, 361, 368, 427, 462, 505, 564, 862, 883, 893, 954, 991, 1037; **VII,** 126, 319, 453, 491; **VIII,** 161, 173, 212, 254; **IX,** 191, 656, 662. Also see OS VI, 968.

17-13 *Dehydrohalogenation of Acyl Halides and Sulfonyl Halides*

HYDRO-HALO-ELIMINATION



Ketenes can be prepared by treatment of acyl halides with tertiary amines.[257] The scope is broad, and most acyl halides possessing an a hydrogen give the reaction, but if at least one R is hydrogen, only the ketene dimer, not the ketene, is isolated. However, if it is desired to use a reactive ketene in a reaction with a given compound, the ketene can be generated *in situ* in the presence of the given compound.[258]

Sulfene

Closely related is the reaction of tertiary amines with sulfonyl halides that contain an a hydrogen. In this case, the initial product is the highly reactive sulfene, which cannot be isolated but reacts further to give products, one of which may be the alkene that is the dimer of RCH.[259] Reactions of sulfenes *in situ* are also common (e.g., see **16-62**).

OS **IV,** 560; **V,** 294, 877; **VI,** 549, 1037; **VII,** 232; **VIII,** 82.

17-14 *Elimination of Boranes*

HYDRO-BORANETRIYL-ELIMINATION

Trialkylboranes are formed from an alkene and BH_3 **(15-16).** When the resulting borane is treated with another alkene, an exchange reaction occurs.[260] This is an equilibrium process that can be shifted by using a large excess of alkene, by using an unusually reactive alkene, or by using an alkene with a higher boiling point than the displaced alkene and removing the latter by distillation. The reaction is useful for shifting a double bond in the direction opposite to that resulting from normal isomerization methods (12-2). This cannot be accomplished simply by treatment of

a borane such as 38 with an alkene, because elimination in this reaction follows Zaitsev's rule: It is in the direction of the most stable alkene, and the product would be 37, not 40. However, if it is desired to convert 37-40, this can be accomplished by converting 37-38, isomerizing 38-39 (18-11) and then subjecting

$$\underset{37}{Et_2C{=}CHCH_3} \longrightarrow \underset{38}{Et_2CHCHCH_3} \longrightarrow \underset{39}{Et_2CHCH_2CH_2} \longrightarrow \underset{40}{Et_2CHCH_2{=}CH_2}$$

39 to the exchange reaction with a higher boiling alkene (e.g., 1-decene), whereupon 40 is produced. In the usual isomerizations (12-2), 40 could be isomerized to 37, but not the other way around. Reactions **38 → 39** and **39 → 40** proceed essentially without rearrangement. The mechanism is probably the reverse of borane addition (15-16).

A similar reaction, but irreversible, has been demonstrated for alkynes.[261]

$$(R_2CH{-}CH_2)_3B + R'C{\equiv}CR' \longrightarrow 3\,R_2C{=}CH_2 + (R'CH{=}CR')_3B$$

17-15 *Conversion of Alkenes to Alkynes*

HYDRO-METHYL-ELIMINATION

$$CH_3{-}\underset{\displaystyle CH_3}{\overset{\displaystyle CH_3}{\overset{|}{\underset{|}{C}}}}{=}\underset{\displaystyle H}{\overset{\displaystyle CH_3}{\overset{|}{\underset{|}{C}}}}{-}CH_2R \xrightarrow[\text{aq.AcOH}]{\text{NaNO}_2} CH_3{-}C{\equiv}C{-}CH_2R$$

Alkenes of the form shown lose the elements of methane when treated with sodium nitrite in acetic acid and water, to form alkynes in moderate-to-high yields.[262] The R may contain additional unsaturation as well as OH, OR, OAc, C=O, and other groups, but the $Me_2C{=}CHCH_2{-}$ portion of the substrate is necessary for the reaction to take place. The mechanism is complex, beginning with a nitration that takes place with allylic rearrangement ($Me_2C{=}CHCH_2R \rightarrow H_2C{=}CMe\ CH(NO_2){-}CH_2R$), and involving several additional intermediates.[263] The CH_3 lost from the substrate appears as CO_2, as demonstrated by the trapping of this gas.[263]

17-16 *Decarbonylation of Acyl Halides*

HYDRO-CHLOROFORMYL-ELIMINATION

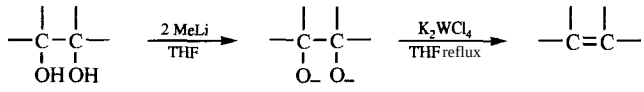
$$RCH_2CH_2COCl + RhCl(Ph_3P)_3 \xrightarrow{\Delta} RCH{=}CH_2 + HCl + RhCl(CO)(Ph_3P)_2$$

Acyl chlorides containing an a hydrogen are smoothly converted to alkenes, with loss of HC1 and CO, on heating with chlorotris(triphenylphosphine)rhodium, with metallic platinum, or with certain other catalysts.[264] The mechanism probably involves conversion of RCH_2CH_2COCl to $RCH_2CH_2{-}RhCO(Ph_3P)_2Cl_2$ followed by a concerted syn elimination of Rh and H.[265] See also 14-39 and **19-12**.

B. *Reactions in Which Neither Leaving Atom Is Hydrogen*

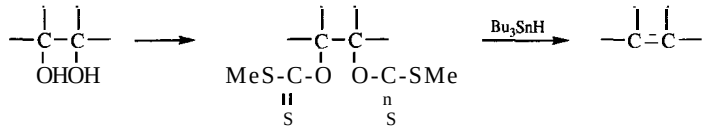
17-17 *Deoxygenation of Vicinal Diols*

DIHYDROXY-ELIMINATION



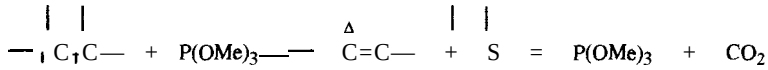
vic-Diols can be deoxygenated by treatment of the dilithium dialkoxide with the tungsten halide K_2WCl_6, or with certain other tungsten reagents, in refluxing THF.[266] Tetrasubstituted diols react most rapidly. The elimination is largely, but not entirely, syn. Several other methods have been reported,[267] in which the diol is deoxygenated directly, without conversion to the dialkoxide. These include treatment with titanium metal,[268] with TsOH–NaI,[269] and by heating with $CpReO_3$.[270]

vic-Diols can also be deoxygenated indirectly, through sulfonate ester derivatives. For example, *vic*-dimesylates and *vic*-ditosylates have been converted to alkenes by treatment, respectively, with naphthalene–sodium[271] and with NaI in DMF.[272] In another procedure, the diols are converted to bis(dithiocarbonates), bis (xanthates), which undergo elimination (probably by a free-radical mechanism) when treated



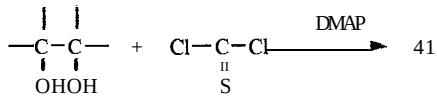
with tri-*n*-butylstannane in toluene or benzene.[273] v/c-Diols can also be deoxygenated through cyclic derivatives (17-18).

17-18 *Cleavage of Cyclic Thionocarbonates*



41

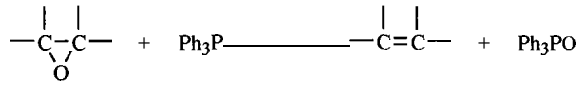
Cyclic thionocarbonates (41) can be cleaved to alkenes (the *Corey-Winter reaction*)[274] by heating with trimethyl phosphite[275] or other trivalent phosphorus compounds[276] or by treatment with bis(l,5-cyclooctadiene)nickel.[277] The thionocarbonates can be prepared by treatment of 1,2-diols with thiophosgene and 4-dimethylaminopyridine (DMAP):[278]



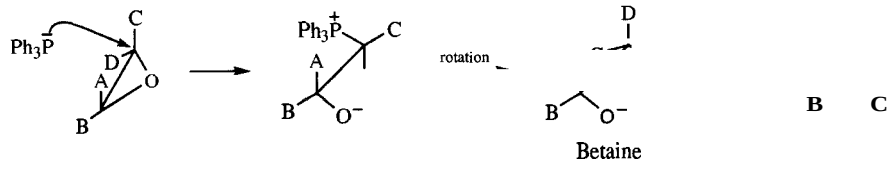
The elimination is of course syn, so the product is sterically controlled. Alkenes that are not sterically favored can be made this way in high yield (e.g., *cis*-$PhCH_2CH{=}CHCH_2Ph$).[279] Certain other five-membered cyclic derivatives of 1,2-diols can also be converted to alkenes.[280]

17-19 *The Conversion of Epoxides and Episulfides to Alkenes*

EPI-OXY-ELIMINATION



Epoxides can be converted to alkenes[281] by treatment with triphenylphosphine[282] or triethyl phosphite $P(OEt)_3$.[283] The first step of the mechanism is nucleophilic substitution (10-50), followed by a four-center elimination. Since inversion accompanies the substitution, the overall elimination is anti, that is, if two groups A and C are cis in the epoxide, they will be trans in the alkene:

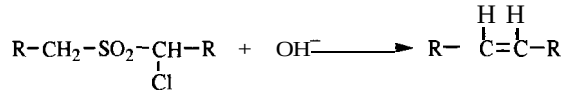


Alternatively, the epoxide can be treated with lithium diphenylphosphide (Ph_2PLi), and the product quaternized with methyl iodide.[284] Alkenes have also been obtained from epoxides by reaction with a large number of reagents,[285] among them Li in THF,[286] TsOH and NaI,[287] trimethylsilyl iodide,[288] PI_3,[289] F_3COOH–NaI,[290] SmI_2,[291] and the tungsten reagents mentioned in **17-17**.[266] Some of these methods give syn elimination. Treatment of cyclooctene oxide with Ph_3P–$OPPh_3$ and NEt_3 gave cyclooctadiene.[292]

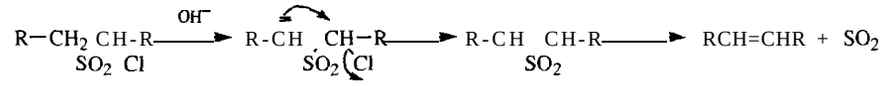
Episulfides[293] can be converted to alkenes.[294] However, in this case the elimination is syn, so the mechanism cannot be the same as that for conversion of epoxides. The phosphite attacks sulfur rather than carbon. Among other reagents that convert episulfides to alkenes are Bu_3SnH,[295] certain rhodium complexes,[296] $LiAlH_4$[297] (this compound behaves quite differently with epoxides, see 10-85), and methyl iodide.[298] Episulfoxides can be converted to alkenes and sulfur monoxide simply by heating.[299]

17-20 *The Ramberg-Bäcklund Reaction*

RAMBERG-BÄCKLUND HALOSULFONE TRANSFORMATION

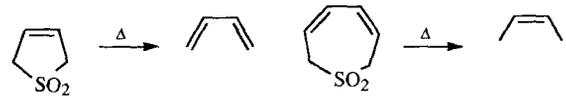


The reaction of an α-halo sulfone with a base to give an alkene is called the *Ramberg–Bäcklund reaction.*[300] The reaction is quite general for a-halo sulfones with an α′ hydrogen, despite the unreactive nature of a-halo sulfones in normal S_N2 reactions (p. 437). Halogen reactivity is in the order $I > Br \gg Cl$. Phase-transfer catalysis has been used.[301] In general, mixtures of cis and trans isomers are obtained, but usually the less stable cis isomer predominates. The mechanism involves formation of an episulfone, and then elimination of SO_2. There is much evidence for



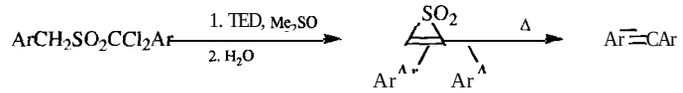
this mechanism,[302] including the isolation of the episulfone intermediate,[303] and the preparation of episulfones in other ways and the demonstration that they give alkenes under the reaction conditions faster than the corresponding a-halo sulfones.[304] Episulfones synthesized in other ways (e.g., **16-62)** are reasonably stable compounds but eliminate SO_2 to give alkenes when heated or treated with base.

If the reaction is run on the unsaturated bromo sulfones ($RCH_2CH{=}CHSO_2CH_2$-Br) (prepared by reaction of $BrCH_2SO_2Br$ with $RCH_2CH{=}CH_2$ followed by treatment with Et_3N), the dienes ($RCH{=}CHCH{=}CH_2$) are produced in moderate-to-good yields.[305] The compound mesyltriflone ($CF_3SO_2CH_2SO_2CH_3$) can be used as a synthon for the tetraion $^{2-}C{=}C^{2-}$. Successive alkylation **(10-104)** converts it to $CF_3SO_2CR^1R^2SO_2CHR^3R^4$ (anywhere from one to four alkyl groups can be put in), which, when treated with base, gives $R^1R^2C{=}CR^3R^4$.[306] The nucleofuge here is the $CF_3SO_2^-$ ion.



42 43

2,5-Dihydrothiophene-l,l-dioxides (42) and 2,17-dihydrothiepin-1,1-dioxides (43) undergo analogous 1,4 and 1,6 eliminations, respectively (see also **17-38).** These are concerted reactions and, as predicted by the orbital-symmetry rules (p. 1067), the former[307] is a suprafacial process and the latter[308] an antarafacial process. The rules also predict that elimination of SO_2 from episulfones cannot take place by a concerted mechanism (except antarafacially, which is unlikely for such a small ring), and the evidence shows that this reaction occurs by a non-concerted pathway.[309] The eliminations of SO_2 from **42** and **43** are examples of *cheletropic reactions,*[310] which are defined as reactions in which two σ bonds that terminate at a single atom (in this case the sulfur atom) are made or broken in concert.[311]



44 45 46

a,a-Dichlorobenzyl sulfones (44) react with an excess of the base triethylene-diamine in DMSO sulfoxide at room temperature to give 2,3-diarylthiiren-l,l-

dioxides (45), which can be isolated.[312] Thermal decomposition of **45** gives the alkynes 46.[313]

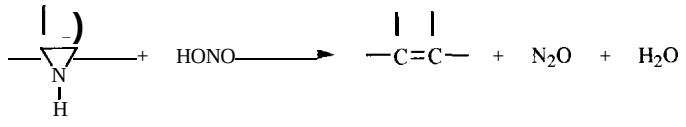
A Ramberg-Bäcklund type reaction has been carried out on the α-halo *sulfides*, $ArCHClSCH_2Ar$, which react with *t*-BuOK and PPh_3 in refluxing THF to give the alkenes ArCH=CHAr.[314]

The Ramberg-Bäcklund reaction can be regarded as a type of extrusion reaction (see p. 1352).

OS **V,** 877; **VI,** 454, 555; **VIII,** 212.

17-21 *The Conversion of Aziridines to Alkenes*

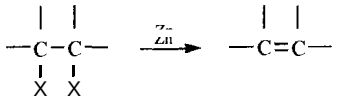
EPI-IMINO-ELIMINATION



Aziridines not substituted on the nitrogen atom react with nitrous acid to produce alkenes.[315] An N-nitroso compound is an intermediate **(12-49);** other reagents that produce such intermediates also give alkenes. The reaction is stereospecific: cis aziridines give cis alkenes and trans aziridines give trans alkenes.[316] Aziridines carrying N-alkyl substituents can be converted to alkenes by treatment with ferrous iodide[317] or with *m*-chloroperoxybenzoic acid.[318] An N-oxide intermediate **(19-27)** is presumably involved in the latter case.

17-22 *Dehalogenation of Vicinal Dihalides*

DIHALO-ELIMINATION



Dehalogenation has been accomplished with many reagents, the most common being zinc, magnesium, and iodide ion.[319] Among reagents used less frequently have been phenyllithium, phenylhydrazine, $CrCl_2$, Na_2S in DMF,[320] and $LiAlH_4$.[321] Electrochemical reduction has also been used.[322] Treatment with In[323] or Sm[324] metal in methanol, a Grignard reagent and $Ni(dppe)Cl_2$,[325] nickel compounds with Bu_3SnH,[326] or SmI_2[327] leads to the alkene. Though the reaction usually gives good yields, it is not very useful because the best way to prepare *vic*-dihalides is by the addition of halogen to a double bond **(15-37).** One useful feature of this reaction is that there is no doubt about the *position* of the new double bond, so that it can be used to give double bonds exactly where they are wanted. For example, allenes, which are not easily prepared by other methods, can be prepared from X–C–CX_2–C–X or X–C–CX=C– systems.[328] Cumulenes have been obtained

from 1,4 elimination:

$$BrCH_2-C\equiv C-CH_2Br + Zn \longrightarrow CH_2=C=C=CH_2$$

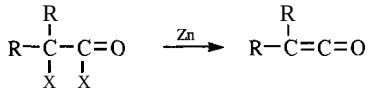
Cumulenes have also been prepared by treating alkynyl epoxides with boron trifluoride.[329] 1,4 Elimination of BrC—C=C—CBr has been used to prepare conjugated dienes (C=C-C=C).[330]

The reaction can be carried out for any combination of halogens, except where one is fluorine. Mechanisms are often complex and depend on the reagent and reaction conditions.[331] For different reagents, mechanisms involving carbocations, carbanions, and free-radical intermediates, as well as concerted mechanisms, have been proposed. When the reagent is zinc, anti stereospecificity has been observed in some cases,[332] but not in others.[333]

OS **III,** 526, 531; IV, 195, 268; V, 22, 255, 393, 901; VI, 310, **VII,** 241. Also see OS IV, 877, 914, 964.

17-23 *Dehalogenation of α-Halo Acyl Halides*

DIHALO-ELIMINATION

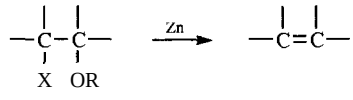


Ketenes can be prepared by dehalogenation of α-halo acyl halides with zinc or with triphenylphosphine.[334] The reaction generally gives good results when the two R groups are aryl or alkyl, but not when either one is hydrogen.[335]

OS **IV,** 348; **VIII,** 377.

17-24 *Elimination of a Halogen and a Hetero Group*

ALKOXY-HALO- ELIMINATION



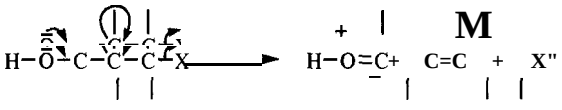
The elimination of OR and halogen from β-halo ethers is called the *Boord reaction.* It can be carried out with zinc, magnesium, sodium, or certain other reagents.[336] The yields are high and the reaction is of broad scope. β-Halo acetals readily yield vinylic ethers $X-\overset{|}{\underset{|}{C}}-\overset{!}{\underset{!}{C}}(OR)_2 \rightarrow -\overset{|}{\underset{|}{C}}=\overset{!}{\underset{!}{C}}-OR$. Besides P-halo ethers, the reaction can also be carried out on compounds of the formula $Z-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-Z$, where X is halogen and Z is OCOR, OTs,[337] NR_2,[338] or SR.[339] The Z group may also be OH, but then X is limited to Br and I. Like **17-22,** this method ensures that the new double bond will be in a specific position. The fact that magnesium causes elimination in these cases limits the preparation of Grignard reagents from these compounds. It has

been shown that treatment of β-halo ethers and esters with zinc gives nonstereospecific elimination,[340] so the mechanism was not E2. An E1cB mechanism was postulated because of the poor leaving-group ability of OR and OCOR. Bromohydrins can be converted to alkenes (elimination of Br, OH) in high yields by treatment with $LiAlH_4$–$TiCl_3$.[341]

OS **III,** 698, IV, 748; VI, 675.

Fragmentations

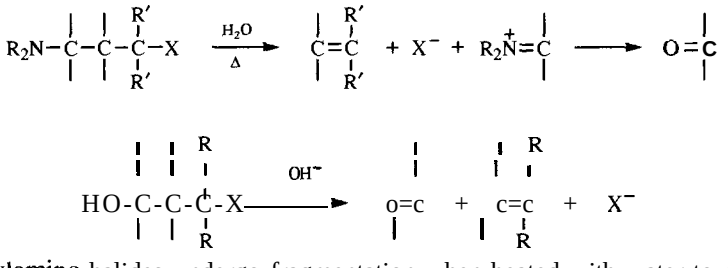
When carbon is the positive leaving group (the electrofuge) in an elimination, the reaction is *called fragmentation.*[342] These processes occur on substrates of the form W–C–C–X, where X is a normal nucleofuge (e.g., halogen, OH_2^+, OTs, NR_3^+, etc.) and W is a positive-carbon electrofuge. In most of the cases W is HO–C– or R_2N–C–, so that the positive charge on the carbon atom is stabilized by the unshared pair of the oxygen or nitrogen, for example,



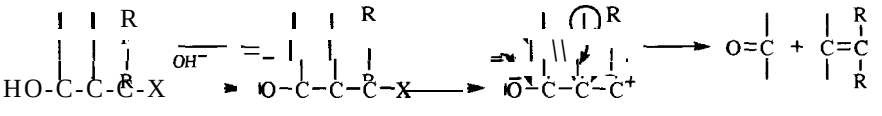
The mechanisms are mostly El or E2. We shall discuss only a few fragmentations, since many are possible and not much work has been done on most of them. Reactions **17-25**–**17-29** and **17-31** may be considered fragmentations. See also **19-12** and **19-13.**

17-25 *Fragmentation of γ-Amino and γ-Hydroxy Halides*

DIALKYLAMINOALKYL-HALO-ELIMINATION, AND SO ON



γ-Dialkylamino halides undergo fragmentation when heated with water to give an alkene and an iminium salt, which under the reaction conditions is hydrolyzed to an aldehyde or ketone (**16-2**).[343] γ-Hydroxy halides and tosylates are fragmented with base. In this instance, the base does not play its usual role in elimination reactions but instead serves to remove a proton from the OH group, which enables the carbon leaving group to come off more easily:

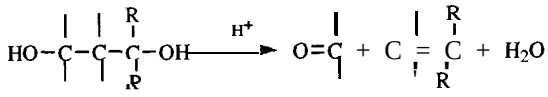


The mechanism of these reactions is often E1. However, in at least some cases, an E2 mechanism operates.[344] It has been shown that stereoisomers of cyclic γ-amino halides and tosylates in which the two leaving groups can assume an anti-periplanar conformation react by the E2 mechanism, while those isomers in which the groups cannot assume such a conformation either fragment by the El mechanism or do not undergo fragmentation at all, but in either case give rise to side products characteristic of carbocations.[345]

γ-Dialkylamino alcohols do not give fragmentation, since for ionization the OH group must be converted to OH_2^+ and this would convert NR_2 to NR_2H^+, which does not have the unshared pair necessary to form the double bond with the carbon.[346]

17-26 Fragmentation of 1,3-Diols

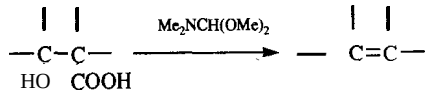
HYDROXYALKYL-HYDROXY-ELIMINATION



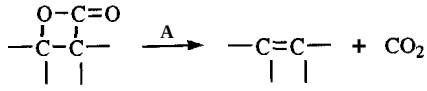
1,3-Diols in which at least one OH group is tertiary or is located on a carbon with aryl substituents can be cleaved by acid treatment.[347] The reaction is most useful synthetically when at least one of the OH groups is on a ring.[348]

17-27 *Decarboxylation of β-Hydroxy Carboxylic Acids and of β-Lactones*

CARBOXY-HYDROXY-ELIMINATION



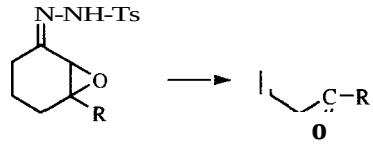
An OH and a COOH group can be eliminated from |3-hydroxy carboxylic acids by refluxing with excess DMF dimethyl acetal.[349] Mono-, di-, tri-, and tetrasubstituted alkenes have been prepared by this method in good yields.[350] There is evidence that the mechanism involves El or E2 elimination from the zwitterionic intermediate $^-O_2C-\overset{|}{C}-\overset{|}{C}-OC=\overset{+}{N}Me_2$.[351] The reaction has also been accomplished[352] under extremely mild conditions (a few seconds at 0°C) with PPh_3 and diethyl azodicarboxylate EtOOC–N=N–COOEt.[353] In a related procedure, |3-lactones undergo thermal decarboxylation to give alkenes in high yields. The reaction has been shown to be a stereospecific syn elimination.[354] There is evidence that this reaction also involves a zwitterionic intermediate.[355]



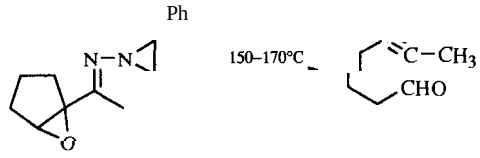
There are no OS references, but see OS VII, 172, for a related reaction.

17-28 *Fragmentation of* α,β-*Epoxy Hydrazones*

ESCHENMOSER-TANABE RING CLEAVAGE



Cyclic α,β-unsaturated ketones[356] can be cleaved by treatment with base of their epoxy tosylhydrazone derivatives to give acetylenic ketones.[357] The reaction can be applied to the formation of acetylenic aldehydes (R=H) by using the corresponding, 2,4-dinitrotosylhydrazone derivatives.[358] Hydrazones (e.g., 47) prepared from



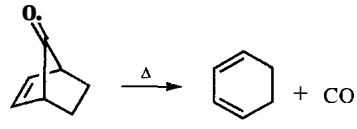
47

epoxy ketones and ring-substituted N-aminoaziridines undergo similar fragmentation when heated.[359]

OS VI, 679.

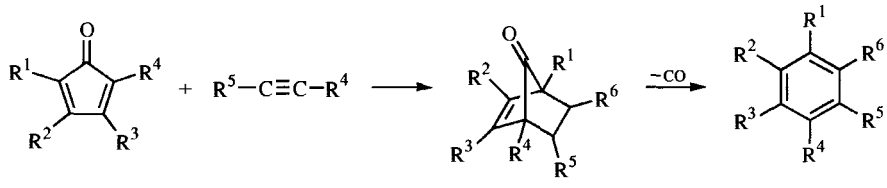
17-29 *Elimination of CO and* CO_2 *from Bridged Bicyclic Compounds*

SECO-CARBONYL-1/4/ELIMINATION



48

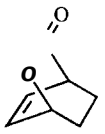
On heating, bicyclo[2.2.1]hept-2,3-en-7-ones (48) usually lose CO to give cyclohexadienes,[360] in a type of reverse Diels–Alder reaction. Bicyclo[2.2.1]heptadienones (49) undergo the reaction so readily (because of the stability of the benzene



49

ring produced) that they cannot generally be isolated. The parent (49) has been obtained at 10–15 K in an Ar matrix, where its spectrum could be studied.[361] Compounds 48 and 49 can be prepared by Diels-Alder reactions between a

cyclopentadienone and an alkyne or alkene, so that this reaction is a useful method for the preparation of specifically substituted benzene rings and cyclohexadienes.[362] Unsaturated bicyclic lactones of the type 50 can also undergo the reaction, losing CO_2. See also **17-37.**



50

OS **III,** 807; V, 604, 1037.

Reversal of the Diels–Alder reaction may be considered a fragmentation. See **15-58.**

Reactions in Which C≡N or C=N Bonds Are Formed

17-30 *Dehydration of Aldoximes and Similar Compounds*

C-HYDRO-*N*-HYDROXY-ELIMINATION

$$\mathrm{R{-}C{-}H} \overset{\mathrm{Ac_2O}}{\longrightarrow} \mathrm{R{-}C{\equiv}N}$$
$$\mathrm{HO{-}N}$$

Aldoximes can be dehydrated to nitriles[363] by many dehydrating agents, of which acetic anhydride is the most common. Among reagents that are effective under mild conditions[364] (room temperature) are Ph_3P-CCl_4,[365] SeO_2,[366] Me_2t-BuSiCl/imidazole,[367] Montmorillonite KSF clay,[368] and chloromethylene dimethylammonium chloride ($Me_2N{=}CHCl^+\ Cl^-$).[369] Microwave irradiation on sulfuric acid impregnated silica gel gives the nitrile.[370] Aldehydes can be converted to oximes *in situ* and microwave irradiation on alumina gives the nitrile.[371] Electrochemical synthesis has also been used.[369] The reaction is most successful when the H and OH are anti. Various alkyl and acyl derivatives of aldoximes, for example, RCH=NOR, RCH=NOCOR, $RCH{=}NOSO_2Ar$, and so on, also give nitriles, as do chlorimines RCH=NCl (the latter with base treatment).[372] N,N-dichloro derivatives of primary amines give nitriles on pyrolysis: $RCH_2NCl_2 \rightarrow$ RCN.[373]

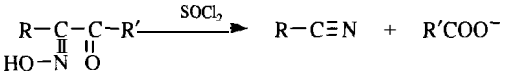
$$\mathrm{R\text{-}C\text{-}H} \overset{\mathrm{OEr}}{\underset{\mathrm{orDBU}}{\longrightarrow}} \mathrm{R\text{-}CEN} + \mathrm{NR_3} + \mathrm{HOEt}$$
$$\mathrm{\| \ N{-}\overset{+}{N}R_3}$$

Quaternary hydrazonium salts (derived from aldehydes) give nitriles when treated with OEt" [374] or DBU (p. 488, 1337):[375] as do dimethylhydrazones $RCH{=}NNMe_2$ when treated with Et_2NLi and HMPA.[376] All these are methods of converting aldehyde derivatives to nitriles. For the conversion of aldehydes directly to nitriles, without isolation of intermediates, see **16-21.**

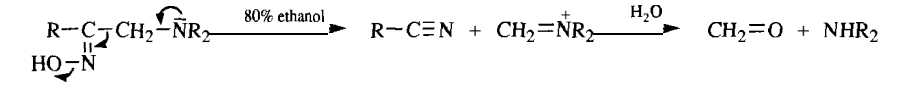
OS **II,** 622; **III,** 690.

17-31 *The Conversion of Ketoximes to Nitriles*

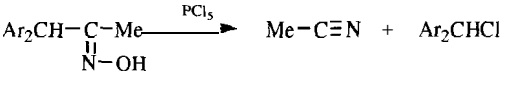
C-ACYL-*N*-HYDROXY-ELIMINATION



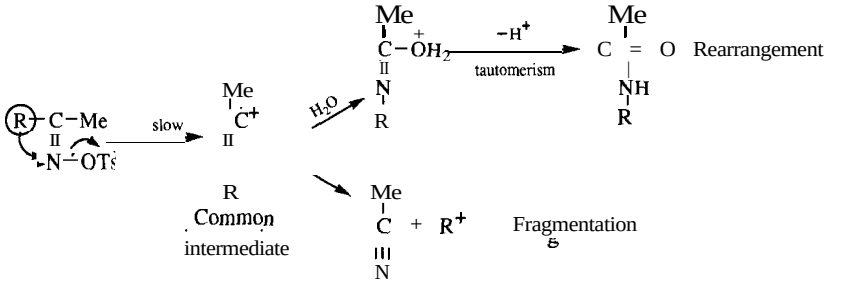
Certain ketoximes can be converted to nitriles by the action of proton or Lewis acids.[377] Among these are oximes of α-diketones (illustrated above), α-keto acids, α-dialkylamino ketones, α-hydroxy ketones, (3-keto ethers, and similar compounds.[378] These are fragmentation reactions, analogous to 17-25 and 17-26. For example, oc-dialkylamino ketoximes also give amines and aldehydes or ketones besides nitriles:[379]



The reaction that normally occurs on treatment of a ketoxime with a Lewis or proton acid is the Beckmann rearrangement (18-17); fragmentations are considered side reactions, often called "abnormal" or "second-order" Beckmann rearrangements.[380] Obviously, the substrates mentioned are much more susceptible to fragmentation than are ordinary ketoximes, since in each case an unshared pair is available to assist in removal of the group cleaving from the carbon. However, fragmentation is a side reaction even with ordinary ketoximes[381] and, in cases where a particularly stable carbocation can be cleaved, may be the main reaction:[382]



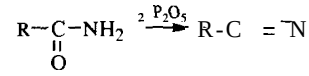
There are indications that the mechanism at least in some cases first involves a rearrangement and then cleavage. The ratio of fragmentation to Beckmann rearrangement of a series of oxime tosylates RC(=NOTs)Me was not related to the solvolysis rate but *was* related to the stability of R^+ (as determined by the solvolysis rate of the corresponding RC1), which showed that fragmentation did not take place in the rate-determining step.[383] It may be postulated then that the first step in the fragmentation and in the rearrangement is the same and that this is the rate-determining step. The product is determined in the second step:



However, in other cases the simple El or E2 mechanisms operate.[384]
OS V, 266; IX, 281.

17-32 *Dehydration of Unsubstituted Amides*

NN-DIHYDRO-*C*-OXO-BIELIMINATION



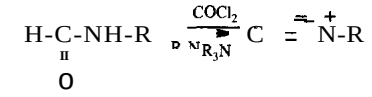
Unsubstituted amides can be dehydrated to nitriles.[385] Phosphorous pentoxide is the most common dehydrating agent for this reaction, but many others, including $POCl_3$, PCl_5, CCl_4—Ph_3P,[386] HMPA,[387] $MeOOCNSO_2NEt_3$ (the Burgess reagent),[388] $Me_2N{=}CHCl^+\ Cl^-$,[389] oxalyl chloride/DMSO/$-78°C$[390] (Swern conditions—see **19-3),** and $SOCl_2$ have also been used.[391] Heating an amide with paraformaldehyde and formic acid gives the nitrile.[392] It is possible to convert an acid to the nitrile, without isolation of the amide, by heating its ammonium salt with the dehydrating agent,[393] or by other methods.[394] Acyl halides can also be directly converted to nitriles by heating with sulfamide, $(NH_2)_2SO_2$.[395] The reaction may be formally looked on as a β-elimination from the enol form of the amide RC(OH)=NH, in which case it is like **17-30,** except that H and OH have changed places. In some cases, for example, with $SOCl_2$, the mechanism probably *is* through the enol form, with the dehydrating agent forming an ester with the OH group, for example, RC(OSOCl)=NH, which undergoes elimination by the El or E2 mechanism.[396] N,N-Disubstituted ureas give cyanamides (R_2N—CO—$NH_2 \rightarrow R_2N$—CN) when dehydrated with $CHCl_3$—NaOH under phase-transfer conditions.[397]

N-Alkyl-substituted amides can be converted to nitriles and alkyl chlorides by treatment with PCl_5. This is called the *von Braun reaction* (not to be confused with the other von Braun reaction, **10-76).**

OS I, 428; **II,** 379; **III,** 493, 535, 584, 646, 768; IV, 62, 144, 166, 172, 436, 486, 706; VI, 304, 465.

17-33 *Conversion of N-Alkylformamides to Isocyanides*

CN-DIHYDRO-*C*-OXO-BIELIMINATION



Isocyanides can be prepared by elimination of water from N-alkylformamides[398] with phosgene and a tertiary amine.[399] Other reagents, among them TsCl in quino-

line, $POCl_3$ and a tertiary amine,[400] $Me_2N{=}CHCl^+\ Cl^-$,[401] triflic anhydride-(i-$Pr)_2NEt$,[402] and Ph_3P-CCl_4-Et_3N[403] have also been employed.

A variation of this process uses carbodiimides,[404] which can be prepared by the dehydration of N,N′-disubstituted ureas with various dehydrating agents,[405] among which are TsCl in pyridine, $POCl_3$, PCl_5, P_2O_5—pyridine, TsCl (with phase-transfer catalysis),[406] and Ph_3PBr_2—Et_3N.[407] Hydrogen sulfide can be removed from the corresponding thioureas by treatment with HgO, NaOCl, or diethyl azodicarboxylate–triphenylphosphine.[408]

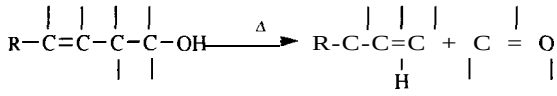
OS V, 300, 772; VI, 620, 751, 987. See also OS **VII,** 27. For the carbodiimide/thiourea dehydration, see OS V, 555; VI, 951.

Reactions in Which C=O Bonds Are Formed

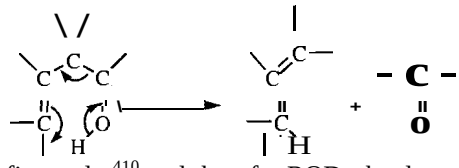
Many elimination reactions in which C=O bonds are formed were considered in Chapter 16, along with their more important reverse reactions. Also see **12-38** and **12-39.**

17-34 *Pyrolysis of β-Hydroxy Alkenes*

O-HYDRO-C-ALLYL-ELIMINATION

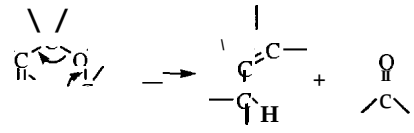


When pyrolyzed, P-hydroxy alkenes cleave to give alkenes and aldehydes or ketones.[409] Alkenes produced this way are quite pure, since there are no side reactions. The mechanism has been shown to be pericyclic, primarily by observations



that the kinetics are first order[410] and that, for ROD, the deuterium appeared in the allylic position of the new alkene.[411] This mechanism is the reverse of that for the oxygen analog of the ene synthesis **(16-53).** β-Hydroxyacetylenes react similarly to give the corresponding allenes and carbonyl compounds.[412] The mechanism is the same despite the linear geometry of the triple bonds.

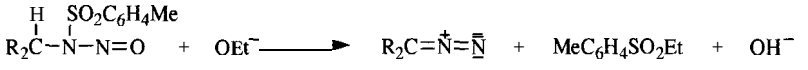
In a related reaction, pyrolysis of allylic ethers that contain at least one a hydrogen gives alkenes and aldehydes or ketones. The mechanism is also pericyclic[413]



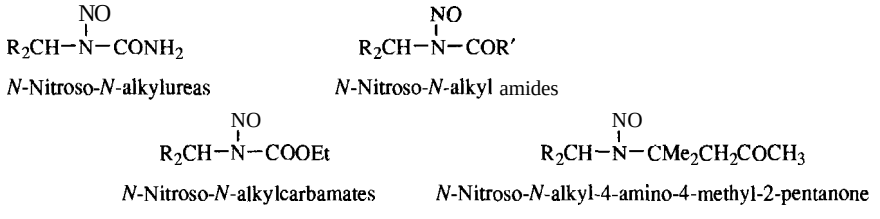
Reactions in Which N=N Bonds Are Formed

17-35 *Eliminations to Give Diazoalkanes*

N-NITROSOAMINE-DIAZOALKANE TRANSFORMATION



Various *N*-nitroso-*N*-alkyl compounds undergo elimination to give diazoalkanes.[414] One of the most convenient methods for the preparation of diazomethane involves base treatment of *N*-nitroso-*N*-methyl-*p*-toluenesulfonamide (illustrated above, with R=H).[415] However, other compounds commonly used are (base treatment is required in all cases):



N-Nitroso-*N*-alkylureas

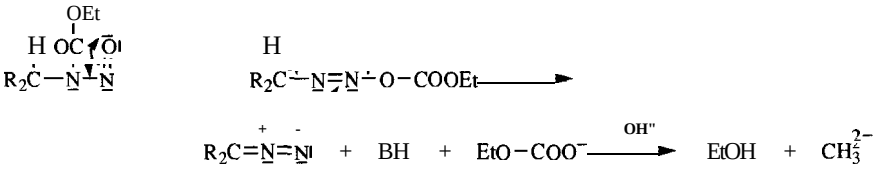
N-Nitroso-*N*-alkyl amides

N-Nitroso-*N*-alkylcarbamates

N-Nitroso-*N*-alkyl-4-amino-4-methyl-2-pentanone

All these compounds can be used to prepare diazomethane, though the sulfonamide, which is commercially available, is most satisfactory. (*N*-Nitroso-*N*-methylcarbamate and *N*-nitroso-*N*-methylurea give good yields, but are highly irritating and carcinogenic.[416]) For higher diazoalkanes the preferred substrates are nitrosoalkylcarbamates.

Most of these reactions probably begin with a 1,3 nitrogen-to-oxygen rearrangement, followed by the actual elimination (illustrated for the carbamate):



OS II, 165; **III,** 119, 244; IV, 225, 250; V, 351; VI, 981.

Extrusion Reactions

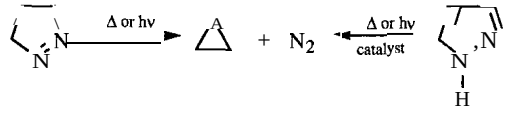
We consider an *extrusion reaction*[417] to be one in which an atom or group Y connected to two other atoms X and Z is lost from a molecule, leading to a product in which X is bonded directly to Z.

Reactions **14-39 and 17-20** also fit this definition. Reaction **17-29** does not fit the definition, but is often also classified as an extrusion reaction. An extrusibility scale

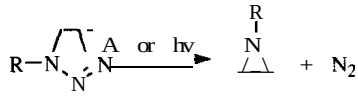
has been developed, showing that the ease of extrusion of the common Y groups is in the order: -N=N- > —COO— > - SO_2— > —CO—.[418]

17-36 *Extrusion of N_2 from Pyrazolines, Pyrazoles, and Triazolines*

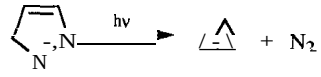
AZO-EXTRUSION



51 52



53



54

1-Pyrazolines (51) can be converted to cyclopropane and N_2 on photolysis[419] or pyrolysis.[420] The tautomeric 2-pyrazolines (52), which are more stable than 51 also give the reaction, but in this case an acidic or basic catalyst is required, the function of which is to convert 52 to 51.[421] In the absence of such catalysts, 52 do not react.[422] In a similar manner, triazolines (53) are converted to aziridines.[423] Side reactions are frequent with both 51 and 53, and some substrates do not give the reaction at all. However, the reaction has proved synthetically useful in many cases. In general, photolysis gives better yields and fewer side reactions than pyrolysis with both 51 and 53. 3*H*-Pyrazoles[424] (54) are stable to heat, but in some cases can be converted to cyclopropenes on photolysis,[425] though in other cases other types of products are obtained.

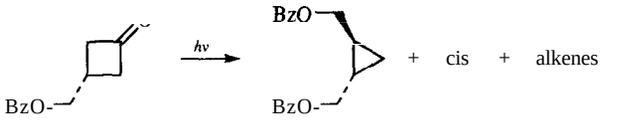
There is much evidence that the mechanism[426] of the 1-pyrazoline reactions generally involves diradicals, though the mode of formation and detailed structure (e.g., singlet vs. triplet) of these radicals may vary with the substrate and reaction conditions. The reactions of the 3*H*-pyrazoles have been postulated to proceed through a diazo compound that loses N_2 to give a vinylic carbene.[427]

55

OS V, 96, 929. See also OS VIII, 597.

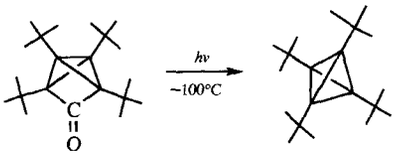
17-37 *Extrusion of CO or CO_2*

CARBONYL-EXTRUSION



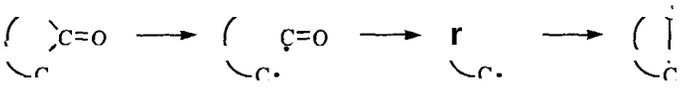
55 56

Though the reaction is not general, certain cyclic ketones can be photolyzed to give ring-contracted products.[428] In the example above, the cyclobutanone (55) was photolyzed to give (56),[429] where BZ is benzoyl. This reaction was used to synthesize tetra-*tert*-butyltetrahedrane **(57).**[430]

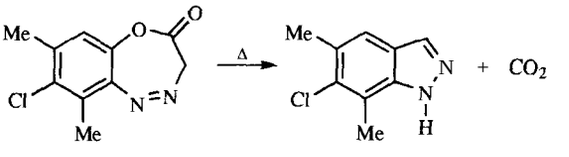


57

The mechanism probably involves a Norrish type I cleavage (p. 318), loss of CO from the resulting radical, and recombination of the radical fragments.



Certain lactones extrude CO_2 on heating or on irradiation, such as the pyrolysis of **58**.[431]

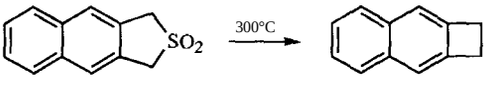


Decarboxylation of β-lactones (see **17-27)** may be regarded as a degenerate example of this reaction. Unsymmetrical diacyl peroxides RCO– OO–COR′ lose two molecules of CO_2 when photolyzed in the solid state to give the product RR'.[432] Electrolysis was also used, but yields were lower. This is an alternative to the Kolbe reaction **(11-37).** See also **17-29** and **17-40.**

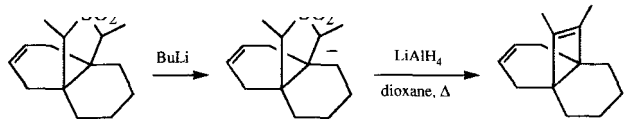
There are no OS references, but see OS VI, 418, for a related reaction.

17-38 *Extrusion of SO_2*

SULFONYL-EXTRUSION



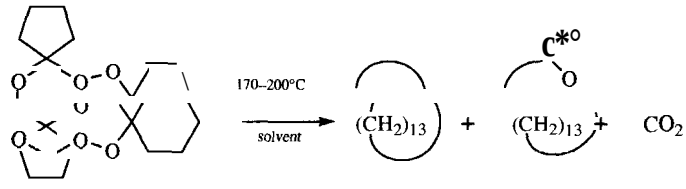
In a reaction similar to **17-37**, certain sulfones, both cyclic and acyclic,[433] extrude SO_2 on heating or photolysis to give ring-contracted products.[434] An example is the preparation of naphtho(*b*)cyclobutene shown above.[435] In a different kind of reaction, five-membered cyclic sulfones can be converted to cyclobutenes by treatment with butyllithium followed by $LiAlH_4$,[436] for example,



This method is most successful when both the α and a' position of the sulfone bear alkyl substituents. See also **17-20.** Treating four-membered ring sultams with $SnCl_2$ led to aziridine products via loss of SO_2.[437]

OS VI, 482.

17-39 *The Story Synthesis*



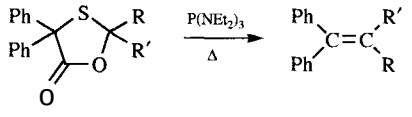
59

When cycloalkylidine peroxides (e.g., 59) are heated in an inert solvent (e.g., decane), extrusion of CO_2 takes place; the products are the cycloalkane containing three carbon atoms less than the starting peroxide and the lactone containing two carbon atoms less[438] (the *Story synthesis).*[439] The two products are formed in comparable yields, usually ~ 15-25% each. Although the yields are low, the reaction is useful because there are not many other ways to prepare large rings. The reaction is versatile, having been used to prepare rings of every size from 8 to 33 members.

Both dimeric and trimeric cycloalkylidine peroxides can be synthesized[440] by treatment of the corresponding cyclic ketones with H_2O_2 in acid solution.[441] The trimeric peroxide is formed first and is subsequently converted to the dimeric compound.[442]

17-40 *Alkene synthesis by Twofold Extrusion*

CARBON DIOXIDE, THIO-EXTRUSION



60

4,4-Diphenyloxathiolan-5-ones (60) give good yields of the corresponding alkenes when heated with tris(diethylamino)phosphine.[443] This reaction is an example of a

general type: alkene synthesis by twofold extrusion of X and Y from a molecule of the type 61.[444] Other examples are photolysis of 1,4-diones[445] (e.g., 62) and treatment of acetoxy sulfones, $RCH(OAc)CH_2SO_2Ph$, with Mg/EtOH and a catalytic amount of $HgCl_2$.[446] Compound 60 can be prepared by the condensation of thiobenzilic acid $Ph_2C(SH)COOH$ with aldehydes or ketones.

[38] This table, which appears in Cockerill, A.F.; Harrison, R.G. Ref. 3, p. 161, was adapted from a longer one in Bordwell, F.G. Ref. 3, p. 375.

[39] $(E1cB)_I$ cannot be distinguished from E2 by this means, because it has the identical rate law: Rate = k[substrate][B^-]. The rate law for $(E1cB)_R$ is different: Rate = fc[substrate][B^-]/[BH], but this is often not useful because the only difference is that the rate is also dependent (inversely) on the concentration of the conjugate acid of the base, and this is usually the solvent, so that changes in its concentration cannot be measured.

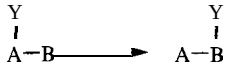
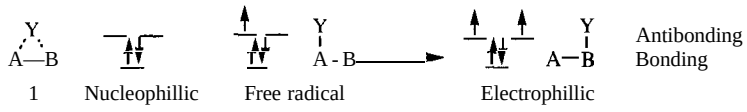
CHAPTER 18

Rearrangements

In a rearrangement reaction, a group moves from one atom to another in the same molecule.[1] Most are migrations from an atom to an adjacent one (called 1,2 shifts), but some are over longer distances. The migrating group (Y) may move with its



electron pair (these can be called *nucleophilic* or *anionotropic* rearrangements; the migrating group can be regarded as a nucleophile), without its electron pair (*electrophilic* or *cationotropic* rearrangements; in the case of migrating hydrogen, *prototropic* rearrangements), or with just one electron (free-radical rearrangements). The atom A is called the *migration origin* and B is the *migration terminus.* However, there are some rearrangements that do not lend themselves to neat categorization in this manner. Among these are those with cyclic transition states **(18-27-18-36).**



1 Nucleophillic Free radical Electrophillic

As we shall see, nucleophilic 1,2 shifts are much more common than electrophilic or free-radical 1,2 shifts. The reason for this can be seen by a consideration of the transition states (or in some cases intermediates) involved. We represent the transition state or intermediate for all three cases by 1, in which the two-electron A–Y bond overlaps with the orbital on atom B, which contains zero, one, and two electrons, in the case of nucleophilic, free-radical, and electrophilic migration, respectively. The overlap of these orbitals gives rise to three new orbitals, which have an energy relationship similar to those on page 58 (one bonding and two degenerate antibonding orbitals). In a nucleophilic migration, where only two electrons are involved, both can go into the bonding orbital and 1 is a low-energy transition state; but in a free-radical or electrophilic migration, there are, respectively, three or four electrons that must be accommodated, and antibonding orbitals must be occupied. It is not surprising therefore that, when 1,2-electrophilic or free-radical shifts are found, the migrating group Y is usually aryl or some other group that can accommodate the extra one or two electrons and thus effectively remove them from the three-membered transition state or intermediate (see 37 on p. 1389).

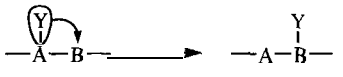
In any rearrangement we can in principle distinguish between two possible modes of reaction: In one of these, the group Y becomes completely detached from A and

may end up on the B atom of a different molecule (*intermolecular* rearrangement); in the other Y goes from A to B in the *same* molecule *(intramolecular* rearrangement), in which case there must be some continuing tie holding W to the A B system, preventing it from coming completely free. Strictly speaking, only the intramolecular type fits our definition of a rearrangement, but the general practice, which is followed here, is to include under the title "rearrangement" all net rearrangements whether they are inter- or intramolecular. It is usually not difficult to tell whether a given rearrangement is inter- or intramolecular. The most common method involves the use of *crossover* experiments. In this type of experiment, rearrangement is carried out on a mixture of Y–A– B and Y′–A–C, where Y' is closely related to Y (say, methyl vs. ethyl) and B to C. In an intramolecular process only A–B–Y and A–C–Y′ are recovered, but if the reaction is intermolecular, then not only will these two be found, but also A–B–Y′ and A–C– Y

MECHANISMS

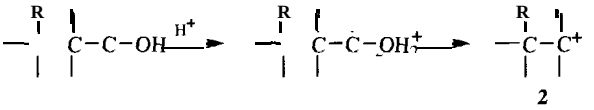
Nucleophilic Rearrangements[2]

Broadly speaking, such rearrangements consist of three steps, of which the actual migration is the second:



This process is sometimes called the *Whitmore 1,2 shift.*[3] Since the migrating group carries the electron pair with it, the migration terminus B must be an atom with only six electrons in its outer shell (an open sextet). The first step therefore is creation of a system with an open sextet. Such a system can arise in various ways, but two of these are the most important:

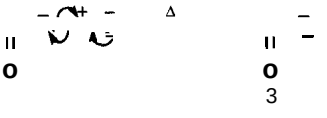
1. *Formation of a Carbocation.* These can be formed in a number of ways (see p. 225), but one of the most common methods when a rearrangement is desired is the acid treatment of an alcohol:



2

These two steps are of course the same as the first two steps of the S_N1 or the El reactions of alcohols.

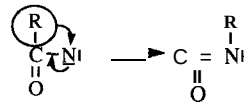
2. *Formation of a Nitrene.* The decomposition of acyl azides is one of several ways in which nitrenes are formed (see p. 253):



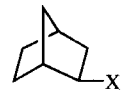
3

After the migration has taken place, the atom at the migration origin (A) must necessarily have an open sextet. In the third step, this atom acquires an octet. In the case of carbocations, the most common third steps are combinations with a nucleophile (rearrangement with substitution) and loss of H^+ (rearrangement with elimination).

Though we have presented this mechanism as taking place in three steps, and some reactions do take place in this way, in many cases two or all three steps are simultaneous. For instance, in the nitrene example above, as the R migrates, an electron pair from the nitrogen moves into the C—N bond to give a stable isocyanate:



In this example, the second and third steps are simultaneous. It is also possible for the second and third steps to be simultaneous even when the "third" step involves more than just a simple motion of a pair of electrons. Similarly, there are many reactions in which the first two steps are simultaneous; that is, there is no actual formation of a species such as 2 or 3. In these instances, it may be said that R assists in the removal of the leaving group, with migration of R and the removal of the leaving group taking place simultaneously. Many investigations have been carried out in attempts to determine, in various reactions, whether such intermediates as 2 or 3 actually form, or whether the steps are simultaneous (see, e.g., the discussions on pp. 1381, 1411), but the difference between the two possibilities is often subtle, and the question is not always easily answered.[4]

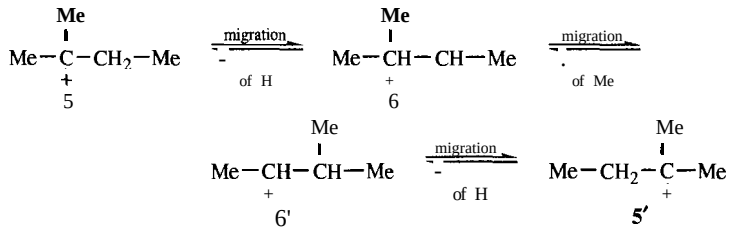


4

Evidence for this mechanism is that rearrangements of this sort occur under conditions where we have previously encountered carbocations: S_N1 conditions, Friedel–Crafts alkylation, and so on. Solvolysis of neopentyl bromide leads to rearrangement products, and the rate increases with increasing ionizing power of the solvent but is unaffected by concentration of base,[5] so that the first step is carbocation formation. The same compound under S_N2 conditions gave no rearrangement, but only ordinary substitution, though slowly. Thus with neopentyl bromide, formation of a carbocation leads only to rearrangement. Carbocations usually rearrange to more stable carbocations. Thus the direction of rearrangement is usually primary —+ secondary → tertiary. Neopentyl (Me_3CCH_2), neophyl ($PhCMe_2$ CH2), and norbornyl (e.g., 4) type systems are especially prone to carbocation rearrangement reactions. It has been shown that the rate of migration increases with the degree of electron deficiency at the migration terminus.[6]

We have previously mentioned (p. 219) that stable tertiary carbocations can be obtained, in solution, at very low temperatures. The NMR studies have shown that when these solutions are warmed, rapid migrations of hydride and of alkyl groups

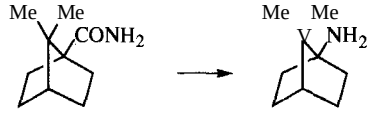
take place, resulting in an equilibrium mixture of structures.[7] For example, the *tert*-pentyl cation (5)[8] equilibrates as follows:



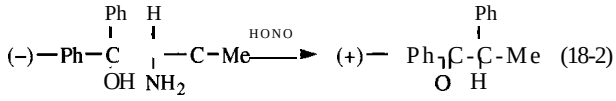
Carbocations that rearrange to give products of identical structure (e.g., **5**⇆**5′**, **6**⇆**6′**) are called *degenerate carbocations* and such rearrangements are *degenerate rearrangements.* Many examples are known.[9]

The Actual Nature of the Migration

Most nucleophilic 1,2 shifts are intramolecular. The W group does not become free but always remains connected in some way to the substrate. Apart from the evidence from crossover experiments, the strongest evidence is that when the group W is chiral, the configuration is *retained* in the product. For example, (+)-PhCHMeCOOH was converted to (−)-$PhCHMeNH_2$ by the Curtius **(18-14),** Hofmann (18-13), Lossen **(18-15),** and Schmidt **(18-16)** reactions.[10] In these reactions, the extent of retention varied from 95.8 to 99.6%. Retention of configuration in the migrating group has been shown many times since.[11] Another experiment demonstrating retention was the easy conversion of **7**–**8**.[11] Neither inversion nor racemization



could take place at a bridgehead. There is much other evidence that retention of configuration usually occurs in W, and inversion never.[12] However, this is not the state of affairs at A and B. In many reactions, of course, the structure of W—A— B is such that the product has only one steric possibility at A or B or both, and in most of these cases nothing can be learned. But in cases where the steric nature of A or B can be investigated, the results are mixed. It has been shown that either inversion or racemization can occur at A or B. Thus the following conversion proceeded with inversion at B:[13]



(18-2)

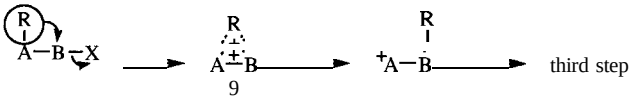
and inversion at A has been shown in other cases.[14] However, in many other cases, racemization occurs at A or B or both.[15] It is not always necessary for the product to have two steric possibilities in order to investigate the stereochemistry at A or B.

Thus, in most Beckmann rearrangements (18-17), only the group trans (usually called anti) to the hydroxyl group migrates:

showing inversion at B.

This information tells us about the degree of concertedness of the three steps of the rearrangement. First consider the migration terminus B. If racemization is found at B, it is probable that the first step takes place before the second and that a positively charged carbon (or other sextet atom) is present at B:

With respect to B, this is an S_N1 type process. If inversion occurs at B, it is likely that the first two steps are concerted, that a carbocation is *not* an intermediate, and that the process is S_N2 like:

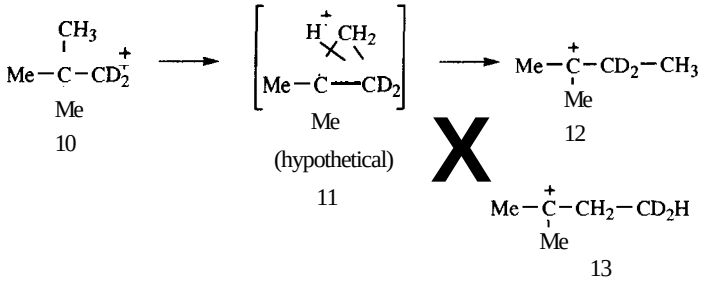


In this case, participation by R assists in removal of X in the same way that neighboring groups do (p. 404). Indeed, R *is* a neighboring group here. The only difference is that, in the case of the neighboring-group mechanism of nucleophilic substitution, R never becomes detached from A, while in a rearrangement the bond between R and A is broken. In either case, the anchimeric assistance results in an increased rate of reaction. Of course, for such a process to take place, R must be in a favorable geometrical position (R and X anti-periplanar). Compound 9 may be a true intermediate or only a transition state, depending on what migrates. In certain cases of the S_N1 type process, it is possible for migration to take place with net retention of configuration at the migrating terminus because of conformational effects in the carbocation.[16]

We may summarize a few conclusions:

1. The S_N1 type process occurs mostly when B is a tertiary atom or has one aryl group and at least one other alkyl or aryl group. In other cases, the S_N2 type process is more likely. Inversion of configuration (indicating an S_N2 type process) has been shown for a neopentyl substrate by the use of the chiral neopentyl-1-*d* alcohol.[17] On the other hand, there is other evidence that neopentyl systems undergo rearrangement by a carbocation (S_N1 type) mechanism.[18]
2. The question as to whether 9 is an intermediate or a transition state has been much debated. When R is aryl or vinyl, then 9 is probably an intermediate and the migrating group lends anchimeric assistance[19] (see p. 414 for resonance stabilization of this intermediate when R is aryl). When R is alkyl, 9 is a

protonated cyclopropane (edge- or corner-protonated; see p. 990). There is much evidence that in simple migrations of a methyl group, the bulk of the products formed do not arise from protonated cyclopropane *intermediates.* Evidence for this statement has already been given (p. 419). Further evidence was obtained from experiments involving labeling.



Rearrangement of the neopentyl cation labeled with deuterium in the 1 position (10) gave only terf-pentyl products with the label in the 3 position (derived from 12), though if 11 were an intermediate, the cyclopropane ring could just as well cleave the other way to give fert-pentyl derivatives labeled in the 4 position (derived from **13**).[20] Another experiment that led to the same conclusion was the generation, in several ways, of $Me_3C^{13}CH_2^+$. In this case, the only fert-pentyl products isolated were labeled in C-3, that is, $Me_2C^+-{}^{13}CH_2CH_3$ derivatives; no derivatives of $Me_2C^+-CH_2^{13}CH_3$ were found.[21]

Though the bulk of the products are not formed from protonated cyclopropane intermediates, there is considerable evidence that at least in 1-propyl systems, a small part of the product can in fact arise from such intermediates.[22] Among this evidence is the isolation of 10-15% cyclopropanes (mentioned on p. 419). Additional evidence comes from propyl cations generated by diazotization of labeled amines ($CH_3CH_2CD_2^+$, $CH_3CD_2CH_2^+$, $CH_3CH_2^{14}CH_2^+$), where isotopic distribution in the products indicated that a small amount (~5%) of the product had to be formed from protonated cyclopropane intermediates, for example,[23]

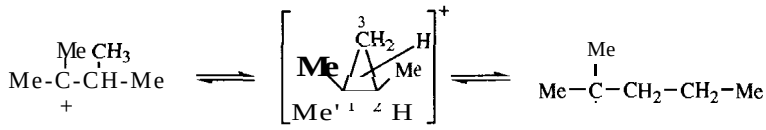
$$CH_3CH_2CD_2NH_2 \xrightarrow{HONO} C_2H_4D-CHD-OH \quad (\approx 1\%)$$

$$CH_3CD_2CH_2NH_2 \xrightarrow{HONO} C_2H_4D-CHD-OH \quad (\approx 1\%)$$

$$CH_3CH_2^{14}CH_2NH_2 \xrightarrow{HONO} {}^{14}CH_3CH_2CH_2OH\ (\approx 2\%) + CH_3{}^{14}CH_2CH_2OH\ (\approx 2\%)$$

Even more scrambling was found in trifluoroacetolysis of 1-propyl-1-^{14}C-mercuric perchlorate.[24] However, protonated cyclopropane intermedi-

ates accounted for $<1\%$ of the products from diazotization of labeled isobutylamine[25] and from formolysis of labeled 1-propyl tosylate.[26]

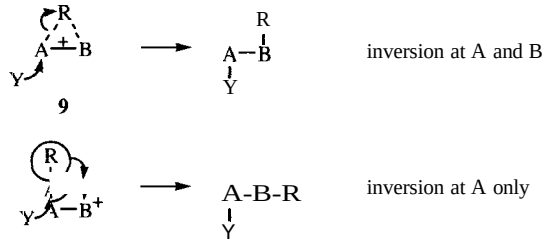


14 15 16

It is likely that protonated cyclopropane transition states or intermediates are also responsible for certain non-1,2 rearrangements. For example, in superacid solution, the ions 14 and 16 are in equilibrium. It is not possible for these to interconvert solely by 1,2 alkyl or hydride shifts unless primary carbocations (which are highly unlikely) are intermediates. However, the reaction can be explained[27] by postulating that (in the forward reaction) it is the 1,2 bond of the intermediate or transition state 15 that opens up rather than the 2,3 bond, which is the one that would open if the reaction were a normal 1,2 shift of a methyl group. In this case, opening of the 1,2 bond produces a tertiary cation, while opening of the 2,3 bond would give a secondary cation. (In the reaction 16 → 14, it is of course the 1,3 bond that opens).

3. There has been much discussion of H as a migrating group. There is no conclusive evidence for the viewpoint that 9 in this case is or is not a true intermediate, though both positions have been argued (see p. 419).

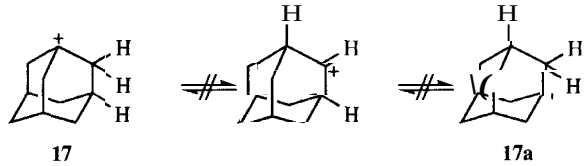
The stereochemistry at the migration origin A is less often involved, since in most cases it does not end up as a tetrahedral atom; but when there is inversion here, there is an S_N2 type process at the beginning of the migration. This may or may not be accompanied by an S_N2 process at the migration terminus B:



9

In some cases, it has been found that, when H is the migrating species, the configuration at A may be *retained*.[28]

There is evidence that the configuration of the molecule may be important even where the leaving group is gone long before migration takes place. For example, the 1-adamantyl cation (17) does not equilibrate intramolecularly, even at temperatures up to 130°C,[29] though open-chain (e.g., $5 \leftrightarrows 5'$) and cyclic tertiary carbocations



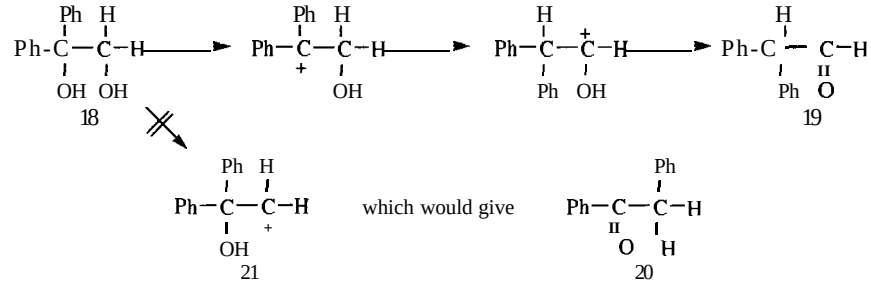
17 17a

undergo such equilibration at 0°C or below. On the basis of this and other evidence, it has been concluded that for a 1,2 shift of hydrogen or methyl to proceed as smoothly as possible, the vacant *p* orbital of the carbon bearing the positive charge and the sp^3 orbital carrying the migrating group must be coplanar,[29] which is not possible for 17.

Migratory Aptitudes[30]

In many reactions, there is no question about which group migrates. For example, in the Hofmann, Curtius, and similar reactions there is only one possible migrating group in each molecule, and one can measure migratory aptitudes only by comparing the relative rearrangement rates of different compounds. In other instances, there are two or more potential migrating groups, but which migrates is settled by the geometry of the molecule. The Beckmann rearrangement **(18-17)** provides an example. As we have seen, only the group trans to the OH migrates. In compounds whose geometry is not restricted in this manner, there still may be eclipsing effects (see p. 1318), so that the choice of migrating group is largely determined by which group is in the right place in the most stable conformation of the molecule.[31] However, in some reactions, especially the Wagner-Meerwein **(18-1)** and the pinacol (18-2) rearrangements, the molecule may contain several groups that, geometrically at least, have approximately equal chances of migrating, and these reactions have often been used for the direct study of relative migratory aptitudes. In the pinacol rearrangement, there is the additional question of which OH group leaves and which does not, since a group can migrate only if the OH group on *the other* carbon is lost.

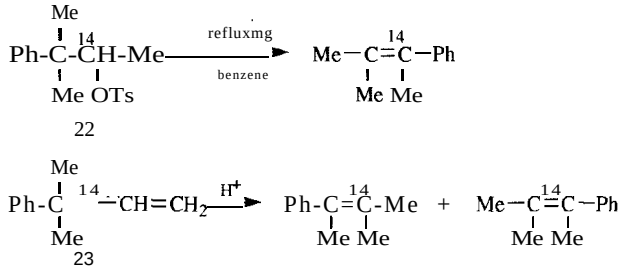
We deal with the second question first. To study this question, the best type of substrate to use is one of the form $R_2C(OH)-CR'_2(OH)$, since the only thing that determines migratory aptitude is which OH group comes off. Once the OH group is gone, the migrating group is determined. As might be expected, the OH that leaves is the one whose loss gives rise to the more stable carbocation. Thus 1,1-diphenylethanediol (18) gives diphenylacetaldehyde (19), not phenylacetophenone (20). Obviously, it does not matter in this case whether phenyl has a greater inherent migratory aptitude



than hydrogen or not. Only the hydrogen can migrate because **21** is not formed. As we know, carbocation stability is enhanced by groups in the order aryl>alkyl>

hydrogen, and this normally determines which side loses the OH group. However, exceptions are known, and which group is lost may depend on the reaction conditions (for an example, see the reaction of 49, p. 1397).

In order to answer the question about inherent migratory aptitudes, the obvious type of substrate to use (in the pinacol rearrangement) is $R'RC(OH)-CRR'(OH)$, since the same carbocation is formed no matter which OH leaves, and it would seem that a direct comparison of the migratory tendencies of R and R' is possible. On closer inspection, however, we can see that several factors are operating. Apart from the question of possible conformational effects, already mentioned, there is also the fact that whether the group R or R' migrates is determined not only by the relative inherent migrating abilities of R and R' but also by whether the group that does *not* migrate is better at stabilizing the positive charge that will now be found at the migration origin.[32] Thus, migration of R gives rise to the cation $R'C^+(OH)CR_2R'_2$, while migration of R' gives the cation $R^+C(OH)CRR'_2$ and these cations have different stabilities. It is possible that in a given case R might be found to migrate less than R', not because it actually has a lower inherent migrating tendency, but because it is much better at stabilizing the positive charge. In addition to this factor,



migrating ability of a group is also related to its capacity to render anchimeric assistance to the departure of the nucleofuge. An example of this effect is the finding that in the decomposition of tosylate 22 only the phenyl group migrates, while in acid treatment of the corresponding alkene (23), there is competitive migration of both methyl and phenyl (in these reactions ^{14}C labeling is necessary to determine which group has migrated).[33] Compounds 22 and 23 give the same carbocation; the differing results must be caused by the fact that in 22 the phenyl group can assist the leaving group, while no such process is possible for 23. This example clearly illustrates the difference between migration to a relatively free terminus and one that proceeds with the migrating group lending anchimeric assistance.[34]

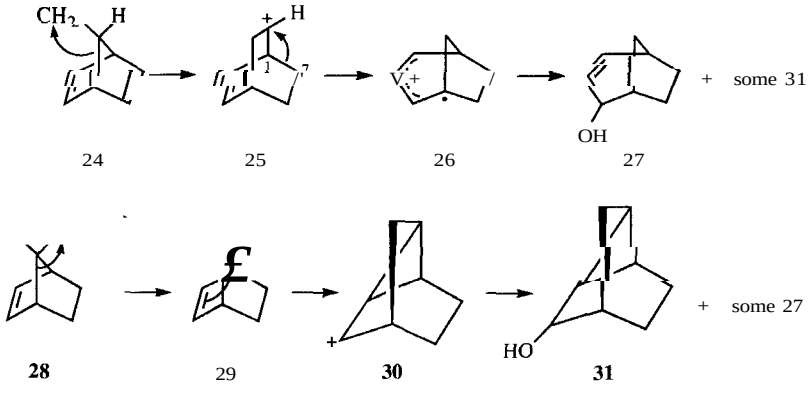
It is not surprising therefore that clear-cut answers as to relative migrating tendencies are not available. More often than not migratory aptitudes are in the order aryl > alkyl, but exceptions are known, and the position of hydrogen in this series is often unpredictable. In some cases, migration of hydrogen is preferred to aryl migration; in other cases migration of alkyl is preferred to that of hydrogen. Mixtures are often found, and the isomer that predominates often depends on conditions. For example, the comparison between methyl and ethyl has been made

many times in various systems, and in some cases methyl migration and in others ethyl migration has been found to predominate.[35] However, it can be said that among aryl migrating groups, electron-donating substituents in the para and meta positions increase the migratory aptitudes, while the same substituents in the ortho positions decrease them. Electron-withdrawing groups decrease migrating ability in all positions. The following are a few of the relative migratory aptitudes determined for aryl groups by Bachmann and Ferguson:[36] *p*-anisyl, 500; *p*-tolyl, 15.7; *m*-tolyl, 1.95; phenyl, 1.00; *p*-chlorophenyl, 0.7; *o*-anisyl, 0.3. For the *o*-anisyl group, the poor migrating ability probably has a steric cause, while for the others there is a fair correlation with activation or deactivation of electrophilic aromatic substitution, which is what the process is with respect to the benzene ring. It has been reported that at least in certain systems acyl groups have a greater migratory aptitude than alkyl groups.[37]

Memory Effects[38]

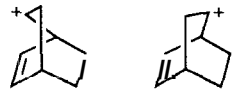
Solvolysis of the endo bicyclic compound (24) (X=ONs, p. 446, or Br) gave mostly the bicyclic allylic alcohol (27), along with a smaller amount of the tricyclic alcohol (31), while solvolysis of the exo isomers (28) gave mostly (31), with smaller amounts of 27.[39] Thus the two isomers gave entirely different ratios of products,

the case of 25, a second rearrangement (a shift of the 1,7 bond) follows, while with 29 what follows is an intramolecular addition of the positive carbon to the double



bond. It seems as if 25 and 29 "remember" how they were formed before they go on to give the second step. Such effects are called *memory effects* and other such cases are known.[40] The causes of these effects are not well understood, though there has been much discussion. One possible cause is differential solvation of the apparently identical ions 25 and 29. Other possibilities are (1) that the ions have geometrical

structures that are twisted in opposite senses (e.g., a twisted 29 might have its positive carbon closer to the double bond than a twisted 25); (2) that ion pairing



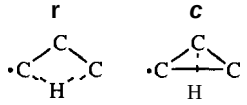
Twisted 29 Twisted 25

is responsible;[41] and (3) that nonclassical carbocations are involved.[42] One possibility that has been ruled out is that the steps 24 → 25 → 26 and 28 → 29 → 30 are concerted, so that 25 and 29 never exist at all. This possibility has been excluded by several kinds of evidence, including the fact that 24 gives not only 27, but also some 31; and 28 gives some 27 along with 31. This means that some of the 25 and 29 ions interconvert, a phenomenon known as *leakage.*

Longer Nucleophilic Rearrangements

The question as to whether a group can migrate with its electron pair from A to C in Y–A–B–C or over longer distances has been much debated. Although claims have been made that alkyl groups can migrate in this way, the evidence is that such migration is extremely rare, if it occurs at all. One experiment that demonstrated this was the generation of the 3,3-dimethyl-1-butyl cation ($Me_3CCH_2CH_2^+$). If 1,3 methyl migrations are possible, this cation would appear to be a favorable substrate, since such a migration would convert a primary cation into the tertiary 2-methyl-2-pentyl cation ($Me_2CCH_2CH_2CH_3$), while the only possible 1,2 migration (of hydride) would give only a secondary cation. However, no products arising from the 2-methyl-2-pentyl cation were found, the only rearranged products being those formed by the 1,2 hydride migration.[43] 1,3 Migration of bromine has been reported.[44]

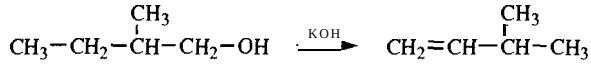
However, most of the debate over the possibility of 1,3 migrations has concerned not methyl or bromine but 1,3 hydride shifts.[45] There is no doubt that *apparent* 1,3 hydride shifts take place (many instances have been found), but the question is whether they are truly direct hydride shifts or whether they occur by another



A B

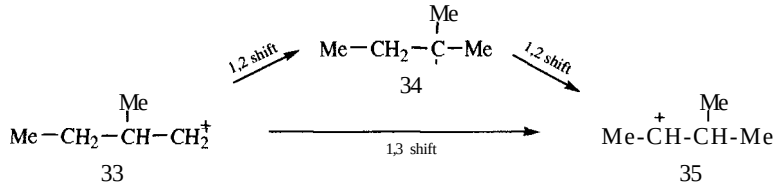
mechanism. There are at least two ways in which indirect 1,3 hydride shifts can take place: (1) by successive 1,2 shifts or (2) through the intervention of protonated cyclopropanes (see p. 1383). A direct 1,3 shift would have the transition state A, while the transition state for a 1,3 shift involving a protonated cyclopropane intermediate would resemble B. The evidence is that most reported 1,3 hydride shifts are actually the result of successive 1,2 migrations,[46] but that in some cases small amounts of products cannot be accounted for in this way. For example, the reaction

of 2-methyl-1-butanol with KOH and bromoform gave a mixture of alkenes, nearly all of which could have arisen from simple elimination or 1,2 shifts of hydride or alkyl. However, 1.2% of the product was 32:[47]



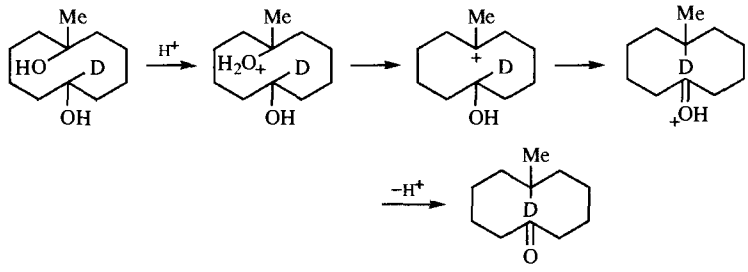
32
(1.2%)

Hypothetically, 32 could have arisen from a 1,3 shift (direct or through a protonated cyclopropane) or from two successive 1,2 shifts:



However, the same reaction applied to 2-methyl-2-butanol gave no 32, which demonstrated that 35 was not formed from 34. The conclusion was thus made that 35 was formed directly from **33.** This experiment does not answer the question as to whether 35 was formed by a direct shift or through a protonated cyclopropane, but from other evidence[48] it appears that 1,3 hydride shifts that do not result from successive 1,2 migrations usually take place through protonated cyclopropane intermediates (which, as we saw on p. 1382, account for only a small percentage of the product in any case). However, there is evidence that direct 1,3 hydride shifts by way of A may take place in superacid solutions.[49]

Although direct nucleophilic rearrangements over distances greater than two adjacent atoms 1,2 are rare (or perhaps nonexistent) when the migrating atom or group must move along a chain, this is not so for a shift across a ring of 8–11 members. Many such transannular rearrangements are known.[50] Several examples are given on page 184. This is the mechanism of one of these:[51]

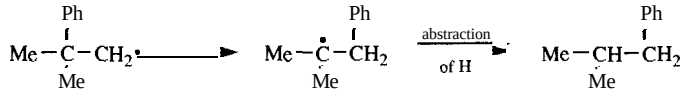


It is noteworthy that the *methyl* group does not migrate in this system. It is generally true that alkyl groups do not undergo transannular migration.[52] In most cases it is hydride that undergoes this type of migration, though a small amount of phenyl migration has also been shown.[53]

Free-Radical Rearrangements[54]

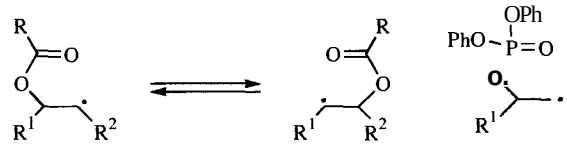
1,2 Free-radical rearrangements are much less common than the nucleophilic type previously considered, for the reasons mentioned on page 1377. Where they do occur, the general pattern is similar. There must first be generation of a free radical, and then the actual migration in which the migrating group moves with one electron:

Finally, the new free radical must stabilize itself by a further reaction. The order of radical stability leads us to predict that here too, as with carbocation rearrangements, any migrations should be in the order primary → secondary → tertiary, and that the logical place to look for them should be in neopentyl and neophyl systems. The most common way of generating free radicals for the purpose of detection of rearrangements is by decarbonylation of aldehydes (14-39). In this manner it was found that neophyl radicals *do* undergo rearrangement. Thus, $PhCMe_2CH_2CHO$ treated with di-*tert*-butyl peroxide gave about equal amounts of the normal product $PhCMe_2CH_3$ and the product arising from migration of phenyl:[55]



Many other cases of free-radical migration of aryl groups have been found.[56]

A 1,2-shift has been observed in radicals bearing an OCOR group at the p-carbon where the oxygen group migrates as shown in the interconversion of 36 and 37. This has been proven by ^{18}O isotopic labeling experiments[57] and other mechanistic explorations.[58] A similar rearrangement was observed with phosphatoxy alkyl radicals such as 38.[59]



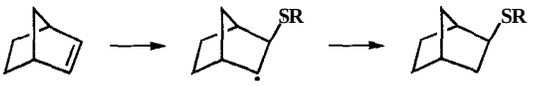
36 37 38

A C → N 1,2-aryl rearrangement was observed when alkyl azides were treated with *n*-Bu_3SnH, proceeding via an C–N·– $SnBu_3$ species to give an imine.[60]

It is noteworthy that the extent of migration is much less than with corresponding carbocations: thus in the example given, there was only ~50% migration, whereas the carbocation would have given much more. Also noteworthy is that there was no migration of the methyl group. In general, it may be said that free-radical migration of alkyl groups does not occur at ordinary temperatures. Many attempts have been made to detect such migration on the traditional neopentyl and bornyl types of substrates. However, alkyl migration is not observed, even in substrates where the corresponding carbocations undergo facile rearrangement.[61] Another type of

migration that is very common for carbocations, but not observed for free radicals, is 1,2 migration of hydrogen. We confine ourselves to a few examples of the lack of migration of alkyl groups and hydrogen:

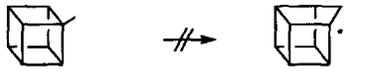
1. 3,3-Dimethylpentanal ($EtCMe_2CH_2CHO$) gave no rearranged products on decarbonylation.[62]
2. Addition of RSH to norbornene gave only *exo*-norbornyl



39

sulfides, though 39 is an intermediate, and the corresponding carbocation cannot be formed without rearrangement.[63]

3. The cubylcarbinyl radical did not rearrange to the 1-homocubyl radical, though



Cubylcarbinyl radical — 1-Homocubyl radical

doing so would result in a considerable decrease in strain.[64]

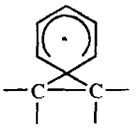
4. It was shown[65] that no rearrangement of isobutyl radical to *tert*-butyl radical (which would involve the formation of a more stable radical by a hydrogen shift) took place during the chlorination of isobutane.

However, 1,2 migration of alkyl groups has been shown to occur in certain *diradicals*.[66] For example, the following rearrangement has been established by tritium labeling.[67]

$$CHT-CH-CH-CH_3 \longrightarrow CH_3-CHT-CH=CH-CH_3$$

In this case, the fact that migration of the methyl group leads directly to a compound in which all electrons are paired undoubtedly contributes to the driving force of the reaction.

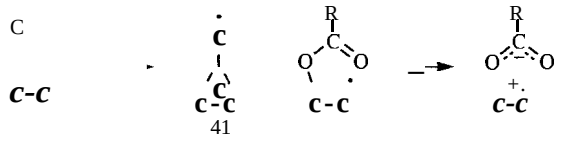
The fact that aryl groups migrate, but alkyl groups and hydrogen generally do not, leads to the proposition that 40, in which the odd electron is not found in the three-membered ring, may be an intermediate. There has been much controversy on this



40

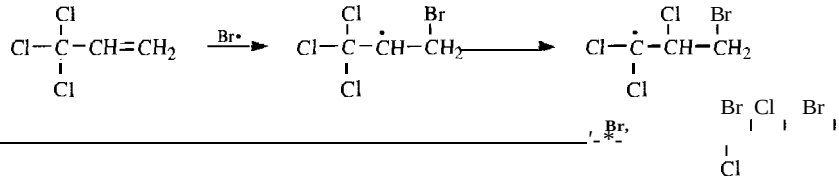
point, but the bulk of the evidence indicates that 40 is a transition state, not an intermediate.[68] Among the evidence is the failure to observe 40 either by ESR[69] or CIDNP.[70] Both of these techniques can detect free radicals with extremely short lifetimes (pp. 238-239).[71]

Besides aryl, vinylic[72] and acetoxy groups[73] also migrate. Vinylic groups migrate by way of a cyclopropylcarbinyl radical intermediate (**41**),[74] while the migration of acetoxy groups may involve the charge-separated structure shown.[75] In addition, migration has been observed for chloro (and to a much lesser extent bromo) groups.



41

For example, in the reaction of $Cl_3CCH{=}CH_2$ with bromine under the influence of peroxides, the products were 47% $Cl_3CCHBrCH_2Br$ (the normal addition product) and 53% $BrCCl_2CHClCH_2Br$, which arose by rearrangement:



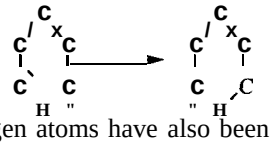
In this particular case, the driving force for the rearrangement is the particular stability of dichloroalkyl free radicals. Freidlina and co-workers[76] have extensively studied reactions of this sort. It has been shown that the 1,2 migration of Cl readily occurs if the migration origin is tertiary and the migration terminus primary.[77] Migration of Cl and Br could take place by a transition state in which the odd electron is accommodated in a vacant *d* orbital of the halogen.

Migratory aptitudes have been measured for the phenyl and vinyl groups, and for three other groups, using the system $RCMe_2CH_2\cdot \rightarrow Me_2\dot{C}CH_2R$. These were found to be in the order $R{=}H_2C{=}CH_2 > Me_3CC{=}O > Ph > Me_3C{\equiv}C > CN$.[78]

In summary then, 1,2 free-radical migrations are much less prevalent than the analogous carbocation processes, and are important only for aryl, vinylic, acetoxy, and halogen migrating groups. The direction of migration is normally toward the more stable radical, but "wrong-way" rearrangements are also known.[79]

Despite the fact that hydrogen atoms do not migrate 1,2, longer free-radical migrations of hydrogen are known.[80] The most common are 1,5 shifts, but 1,6 and longer shifts have also been found. The possibility of 1,3 hydrogen shifts has been much investigated, but it is not certain if any actually occur. If they do they are rare, presumably because the most favorable geometry for C—H—C in the transition state is linear and this geometry cannot be achieved in a 1,3 shift. The 1,4 shifts are definitely known, but are still not very common. These long shifts are best regarded

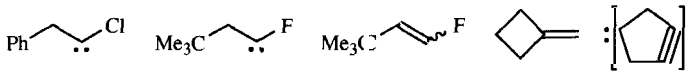
as internal abstractions of hydrogen (for reactions involving them, see **14-7** and **18-40):**



Transannular shifts of hydrogen atoms have also been observed.[81]

Carbene Rearrangements

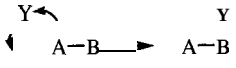
Carbenes can rearrange to alkenes in many cases. A 1,2-hydrogen shift leads to an alkene, and this is often competitive with insertion reactions.[82] Benzylchlorocarbene (42) rearranges via a 1,2-hydrogen shift to give the alkene.[83] Similarly, carbene (43) rearranges to alkene (44), and replacement of H on the α-carbon with D showed a deuterium isotope effect of ~ 5.[84] Rearrangement of alkylidne carbene (45) has been calculated to give the highly unstable cyclopentyne (46), which cannot be isolated, but can give a [2 + 2] cycloaddition product when generated in the presence of a simple alkene.[85]



42 43 44 45 46

Electrophilic Rearrangements[86]

Rearrangements in which a group migrates without its electrons are much rarer than the two kinds previously considered, but the general principles are the same. A carbanion (or other negative ion) is created first, and the actual rearrangement step involves migration of a group without its electrons:



The product of the rearrangement may be stable or may react further, depending on its nature (see also pp. 1396). An *ab initio* study predicts that a [l,2]-alkyl shift in alkyne anions should be facile.[87]

REACTIONS

The reactions in this chapter are classified into three main groups. The 1,2 shifts are considered first. Within this group, reactions are classified according to (1) the identity of the substrate atoms A and B and (2) the nature of the migrating group Y. In the second group are the cyclic rearrangements. The third group consists of rearrangements that cannot be fitted into either of the first two categories.

Reactions in which the migration terminus is on an aromatic ring have been treated under aromatic substitution. These are **11-30-11-35, 11-39, 13-21-13-24,**

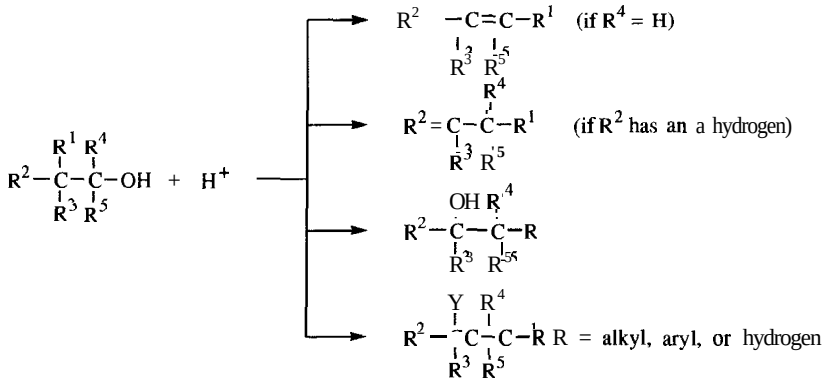
and, partially, **11-36**, **11-41**, and **11-42.** Double-bond shifts have also been treated in other chapters, though they may be considered rearrangements (pp. 327, 776, and **12-2).** Other reactions that may be regarded as rearrangements are the Pummerer **(19-62)** and Willgerodt **(19-63)** reactions.

1,2 Rearrangements

A. *Carbon-to-Carbon Migrations of R, H, and Ar*

18-1 *Wagner-Meerwein and Related Reactions*

1/HYDRO,1/HYDROXY-(2/ → 1/ALKYL)-*MIGRO*-ELIMINATION, AND SO ON



When alcohols are treated with acids, simple substitution (e.g., **10-70)** or elimination **(17-1)** usually accounts for most or all of the products. But in many cases, especially where two or three alkyl or aryl groups are on the β carbon, some or all of the product is rearranged. These rearrangements are called *Wagner-Meerwein rearrangements.* As pointed out previously, the carbocation that is a direct product of the rearrangement must stabilize itself, and most often it does this by the loss of a hydrogen (3 to it, so the rearrangement product is usually an alkene.[88] The proton lost may be R^4 (if this is a hydrogen) or an a proton from R^2 (if it has one). If there is a choice of protons, Zaitsev's rule (p. 1314) governs the direction, as we might expect. Sometimes a different positive group is lost instead of a proton. Less often, the new carbocation stabilizes itself by combining with a nucleophile instead of losing a proton. The nucleophile may be the water that is the original leaving group, so that the product is a rearranged alcohol, or it may be some other species present, which we have called Y. Rearrangement is usually predominant in neopentyl and neophyl types of substrates, and with these types normal nucleophilic substitution is difficult (normal elimination is of course impossible). Under S_N2 conditions, substitution is extremely slow;[89] under S_N1 conditions, carbocations are formed that rapidly rearrange. However, free-radical substitution, unaccompanied by rearrangement, can be carried out on neopentyl systems, though, as we have seen (p. 1389), neophyl systems undergo rearrangement as well as substitution.

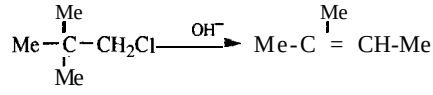
Wagner-Meerwein rearrangements were first discovered in the bicyclic terpenes, and most of the early development of this reaction was with these compounds.[90] An example is

Example *a*

Isobomeol Camphene

Examples in simpler systems are

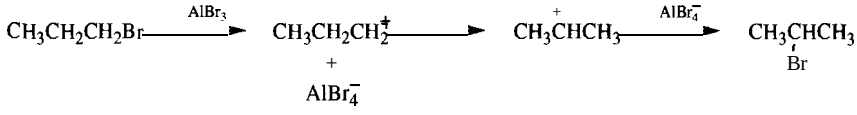
Example *b*



Example *c*

These examples illustrate the following points:

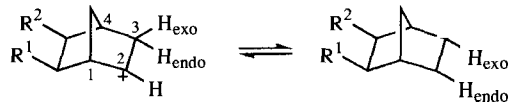
1. Hydride ion can migrate. In example *c,* it was hydride that shifted, not bromine:



2. The leaving group does not have to be H_2O, but can be any departing species whose loss creates a carbocation, including N_2 from aliphatic diazonium ions[91] (see the section on leaving groups in nucleophilic substitution, p. 446). Also, rearrangement may follow when the carbocation is created by addition of a proton or other positive species to a double bond. Even alkanes give rearrangements when heated with Lewis acids, provided some species is initially present to form a carbocation from the alkane.
3. Example *c* illustrates that the last step can be substitution instead of elimination.
4. Example *b* illustrates that the new double bond is formed in accord with Zaitsev's rule.

2-Norbornyl cations, besides displaying the 1,2 shifts of a CH_2 group previously illustrated for the isoborneol → camphene conversion, are also prone to rapid hydride shifts from the 3 to the 2 position (known as 3,2 shifts). These 3,2 shifts usually take place from the exo side;[92] that is, the 3-exo hydrogen migrates to the 2-exo position.[93] This stereoselectivity is analogous to the behavior we have previously

seen for norbornyl systems, namely, that nucleophiles attack norbornyl cations from

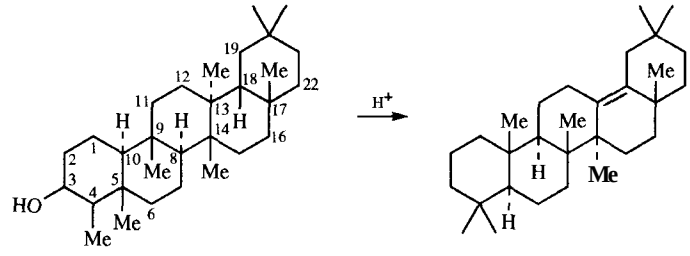


the exo side (p. 415) and that addition to norbornenes is also usually from the exo direction (p. 987).

The direction of rearrangement is usually toward the most stable carbocation (or radical), which is tertiary > secondary > primary, but rearrangements in the other direction have also been found,[94] and often the product is a mixture corresponding to an equilibrium mixture of the possible carbocations.

The term "Wagner-Meerwein rearrangement" is not precise. Some use it to refer to all the rearrangements in this section and in 18-2. Others use it only when an alcohol is converted to a rearranged alkene. Terpene chemists call the migration of a methyl group the *Nametkin rearrangement.* The term *retropinacol rearrangement* is often applied to some or all of these. Fortunately, this disparity in nomenclature does not seem to cause much confusion.

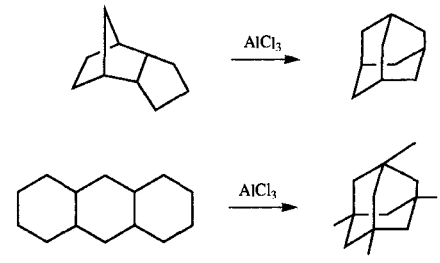
Sometimes several of these rearrangements occur in one molecule, either simultaneously or in rapid succession. A spectacular example is found in the triterpene series. Friedelin is a triterpenoid ketone found in cork. Reduction gives 3β-friedelanol (47). When this compound is treated with acid, 13(18)-oleanene (48) is formed.[95] In this case *seven* 1,2 shifts take place. On removal of H_2O from position 3 to leave a positive charge, the following shifts occur: hydride from 4 to 3; methyl



47 48

from 5 to 4; hydride from 10 to 5; methyl from 9 to 10; hydride from 8 to 9; methyl from 14 to 8; and methyl from 13 to 14. This leaves a positive charge at position 13, which is stabilized by loss of the proton at the 18 position to give 48. All these shifts are stereospecific, the group always migrating on the side of the ring system on which it is located; that is, a group above the "plane" of the ring system (indicated by a solid line in 47) moves above the plane, and a group below the plane (dashed line) moves below it. It is probable that the seven shifts are not all concerted, though some of them may be, for intermediate products can be isolated.[96] As an illustration of point 2 (p. 1394), it may be mentioned that friedelene, derived from dehydration of 47, also gives 48 on treatment with acid.[97]

It was mentioned above that even alkanes undergo Wagner-Meerwein rearrangements if treated with Lewis acids and a small amount of initiator. An interesting application of this reaction is the conversion of tricyclic molecules to adamantane and its derivatives.[98] It has been found that *all* tricyclic alkanes containing 10 carbons are converted to adamantane by treatment with a Lewis acid such as $AlCl_3$. If the substrate contains more than 10 carbons, alkyl-substituted adamantanes are produced. The IUPAC name for these reactions is *Schleyer adamantization.* Two examples are



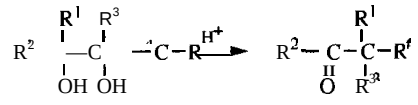
If 14 or more carbons are present, the product may be diamantane or a substituted diamantane.[99] These reactions are successful because of the high thermodynamic stability of adamantane, diamantane, and similar diamond-like molecules. The most stable of a set of C_nH_m isomers (called the *stabilomer*) will be the end product if the reaction reaches equilibrium.[100] Best yields are obtained by the use of "sludge" catalysts[101] (i.e., a mixture of AlX_3 and *tert*-butyl bromide or sec-butyl bromide).[102] Though it is certain that these adamantane-forming reactions take place by nucleophilic 1,2 shifts, the exact pathways are not easy to unravel because of their complexity.[103] Treatment of adamantane-2-^{14}C with $AlCl_3$ results in total carbon scrambling on a statistical basis.[104]

As already indicated, the mechanism of the Wagner-Meerwein rearrangement is usually nucleophilic. Free-radical rearrangements are also known (see the mechanism section of this chapter), though virtually only with aryl migration. However, carbanion mechanisms (electrophilic) have also been found.[86] Thus Ph_3CCH_2Cl treated with sodium gave Ph_2CHCH_2Ph along with unrearranged products.[105] This is called the *Grovenstein-Zimmerman rearrangement.* The intermediate is $Ph_3CCH_2^-$, and the phenyl moves without its electron pair. Only aryl and vinylic,[106] and not alkyl, groups migrate by the electrophilic mechanism (p. 1377) and transition states or intermediates analogous to 40 and 41 are likely.[107]

OS V, 16, 194; VI, 378, 845.

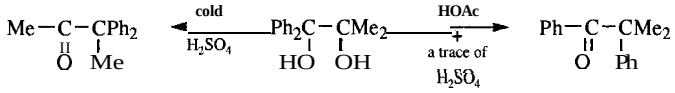
18-2 *The Pinacol Rearrangement*

1/*O*-HYDRO,3/HYDROXY-(2/→ 3/ALKYL)-*MIGRO*-ELIMINATION



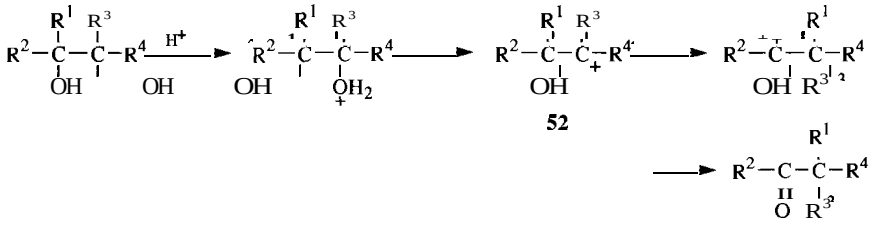
R = alkyl, aryl, or hydrogen

When *vic*-diols (glycols) are treated with acids,[108] they can be rearranged to give aldehydes or ketones, though elimination without rearrangement can also be accomplished. This reaction is called the *pinacol rearrangement;* the reaction gets its name from the typical compound pinacol ($Me_2COHCOHMe_2$), which is rearranged to pinacolone Me_3CCOCH_3).[109] The reaction has been accomplished many times, with alkyl, aryl, hydrogen, and even ethoxycarbonyl (COOEt)[110] as migrating groups. In most cases, each carbon has at least one alkyl or aryl group, and the reaction is most often carried out with tri- and tetrasubstituted glycols. As mentioned earlier, glycols in which the four R groups are not identical can give rise to more than one product, depending on which group migrates (see p. 1384 for a discussion of migratory aptitudes). Stereodifferentiation is possible in this reaction.[111] When TMSOTf was used to initiate the reaction, it was shown to be highly regioselective.[112] Mixtures are often produced, and which group preferentially migrates may depend on the reaction conditions as well as on the nature of the substrate. Thus the action of cold,



50 49 51

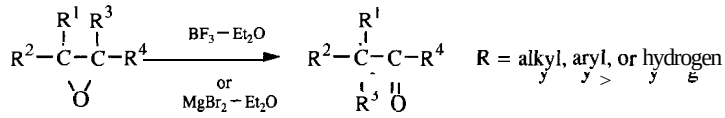
concentrated sulfuric acid on 49 produces mainly the ketone (50) (methyl migration), while treatment of 49 with acetic acid containing a trace of sulfuric acid gives mostly 51 (phenyl migration).[113] If at least one R is hydrogen, aldehydes can be produced as well as ketones. Generally, aldehyde formation is favored by the use of mild conditions (lower temperatures, weaker acids), because under more drastic conditions the aldehydes may be converted to ketones (18-4). The reaction has been carried out in the solid state, by treating solid substrates with HC1 gas or with an organic solid acid.[114]



The mechanism involves a simple 1,2 shift. The ion (52, where all four R groups are Me) has been trapped by the addition of tetrahydrothiophene.[115] It may seem odd that a migration takes place when the positive charge is already at a tertiary position, but carbocations stabilized by an oxygen atom are even more stable than tertiary alkyl cations (p. 323). There is also the driving force supplied by the fact that the new carbocation can immediately stabilize itself by losing a proton.

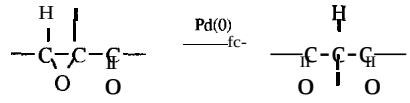
It is obvious that other compounds in which a positive charge can be placed on a carbon α to one bearing an OH group can also give this rearrangement. This is true for p-amino alcohols, which rearrange on treatment with nitrous acid (this is called the *semipinacol* rearrangement), iodohydrins, for which the reagent is mercuric

oxide or silver nitrate, β-hydroxyalkyl selenides, $R^1R^2C(OH)C(SeR^5)R^3R^4$,[116] and allylic alcohols, which can rearrange on treatment with a strong acid that protonates the double bond. A similar rearrangement is given by epoxides, when treated with



acidic[117] reagents such as BF_3—etherate or $MgBr_2$— etherate, 5 *M* $LiClO_4$ in ether,[118] $InCl_3$,[119] or sometimes by heat alone.[120] A related rearrangement called the *Meinwald rearrangement* was induced by the enzyme pig liver esterase.[121] It has been shown that epoxides are intermediates in the pinacol rearrangements of certain glycols.[122] Among the evidence for the mechanism given is that $Me_2COHCOHMe_2$, $Me_2COHCNH_2Me_2$, and $Me_2COHCClMe_2$ gave the reaction at different rates (as expected) but yielded the *same mixture* of two products (pinacol and pinacolone) indicating a common intermediate.[123]

Epoxides can also be rearranged to aldehydes or ketones on treatment with certain metallic catalysts.[124] A good way to prepare p-diketones consists of heating α,β-epoxy ketones at 80-140°C in toluene with small amounts of $(Ph_3P)_4Pd$ and 1,2-bis(diphenylphosphino)ethane.[125]



P-Hydroxy ketones can be prepared by treating the silyl ethers (53) of α,β-epoxy alcohols with $TiCl_4$.[126]

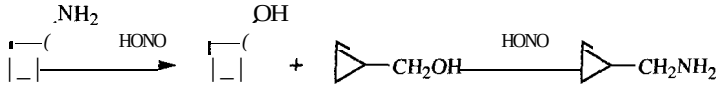
18-3 *Expansion and Contraction of Rings*

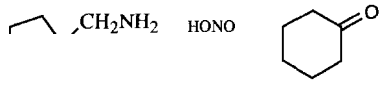
DEMYANOV RING CONTRACTION; DEMYANOV RING EXPANSION



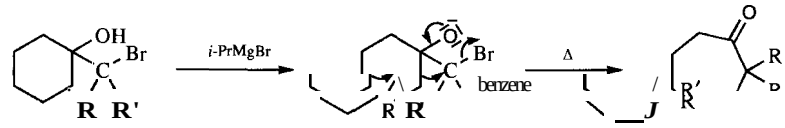
When a positive charge is formed on an alicyclic carbon, migration of an alkyl group can take place to give ring contraction, producing a ring that is one carbon smaller than the original

Note that this change involves conversion of a secondary to a primary carbocation. In a similar manner, when a positive charge is placed on a carbon a to an alicyclic ring, ring expansion can take place.[127] The new carbocation, and the old one, can then give products by combination with a nucleophile (e.g., the alcohols shown above), or by elimination, so that this reaction is a special case of 18-1. Often, both rearranged and unrearranged products are formed, so that, for example, cyclobutylamine and cyclopropylmethylamine give similar mixtures of the two alcohols shown above on treatment with nitrous acid (a small amount of 3-buten-1-ol is also produced). When the carbocation is formed by diazotization of an amine, the reaction is called the *Demyanov rearrangement*,[128] but of course similar products are formed when the carbocation is generated in other ways. The expansion reaction has been performed on rings of C_3 to C_8,[129] but yields are best with the smaller rings, where relief of small-angle strain provides a driving force for the reaction. The contraction reaction has been applied to four-membered rings and to rings of C_6 to C_8, but contraction of a cyclopentyl cation to a cyclobutylmethyl system is generally not feasible because of the additional strain involved. Strain is apparently much less of a factor in the cyclobutyl–cyclopropylmethyl interconversion (for a discussion of this interconversion, see p. 408). The influence of substituents on this rearrangement has been examined.[130]

Ring expansions of certain hydroxyamines, for example, are analogous to the

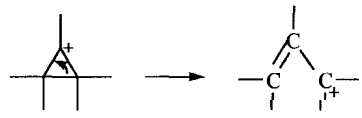


semipinacol rearrangement (18-2). This reaction is called the *Tiffeneau–Demyanov ring expansion.* These have been performed on rings of C_4 to C_8 and the yields are better than for the simple Demyanov ring expansion. A similar reaction has been used to expand rings of from five to eight members.[131] In this case, a cyclic bromohydrin of the form 54 is treated with a Grignard reagent which, acting as a base, removes the OH proton to give the alkoxide 55. Refluxing of 55 brings about the ring enlargement. The reaction has been accomplished for 54 in which at least one R group is phenyl or methyl,[132] but fails when both R groups are hydrogen.[133]



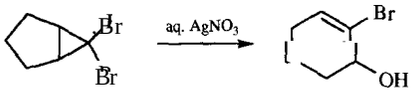
54 55

A positive charge generated on a three-membered ring gives "contraction" to an allylic cation.[134]



We have previously seen (p. 437) that this is the reason nucleophilic substitutions are not feasible at a cyclopropyl substrate. The reaction is often used to convert

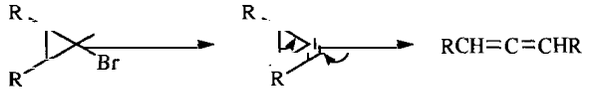
cyclopropyl halides and tosylates to allylic products, especially for the purpose of ring expansion, an example being[135]



The stereochemistry of these cyclopropyl cleavages is governed by the principle of orbital symmetry conservation (for a discussion, see p. 1434).

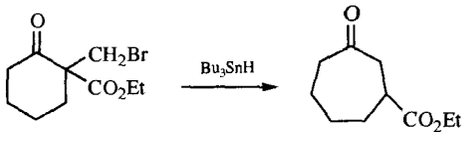
Three-membered rings can also be cleaved to unsaturated products in at least two other ways. (1) On pyrolysis, cyclopropanes can undergo "contraction" to propenes.[136] In the simplest case, cyclopropane gives propene when heated to 400–500°C. The mechanism is generally regarded[137] as involving a diradical

intermediate[138] (recall that free-radical 1,2 migration is possible for diradicals, p. 1389). (2) The generation of a carbene or carbenoid carbon in a three-membered ring can lead to allenes, and allenes are often prepared in this way.[139] Flash vacuum

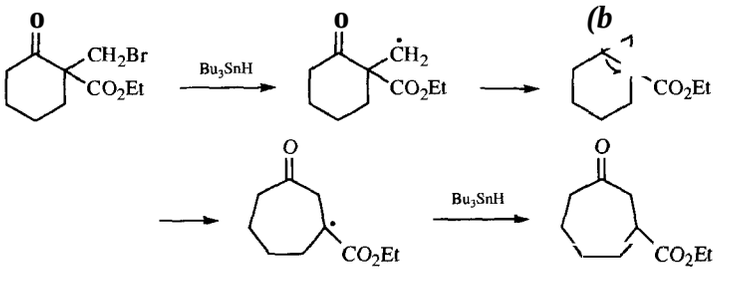


pyrolysis of 1-chlorocyclopropene thermally rearranges to chloroallene.[140] One way to generate such a species is treatment of a 1,1-dihalocyclopropane with an alkyllithium compound (**12-37**).[141] In contrast, the generation of a carbene or carbenoid at a cyclopropylmethyl carbon gives ring expansion.[142]

Some free-radical ring enlargements are also known, an example being:[143]



This reaction has been used to make rings of 6, 7, 8, and 13 members. A possible mechanism is



This reaction has been extended to the expansion of rings by three or four carbons, by the use of a substrate containing $(CH_2)_nX$ (n = 3 or 4) instead of CH_2Br.[144] By this means, 5-, 6-, and 7-membered rings were enlarged to 18- to 11-membered rings.

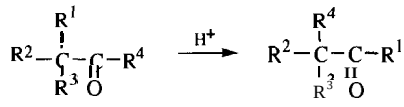
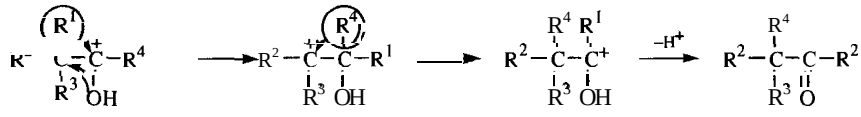
18-4 *Acid-Catalyzed Rearrangements of Aldehydes and Ketones*

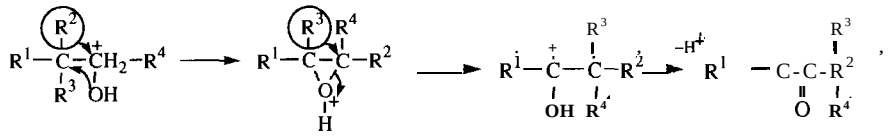
1/ALKYL,2/ALKYL-INTERCHANGE, AND SO ON



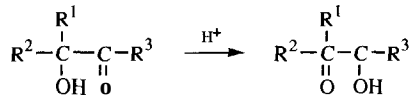
Rearrangements of this type, where a group a to a carbonyl "changes places" with a group attached to the carbonyl carbon, occur when migratory aptitudes are favorable.[145] The R^2, R^3, and R^4 groups may be alkyl or hydrogen. Certain aldehydes have been converted to ketones, and ketones to other ketones (though more drastic conditions are required for the latter), but no rearrangement of a ketone to an aldehyde ($R^1 = H$) has so far been reported. There are two mechanisms,[146] each beginning with protonation of the oxygen and each involving two migrations. In one pathway, the migrations are in opposite directions:[147]



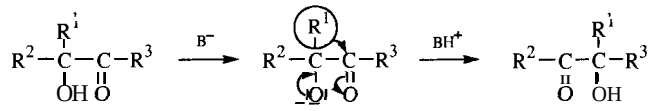
In the other pathway, the migrations are in the same direction. The actual mechanism of this pathway is not certain, but an epoxide (protonated) intermediate[148] is one possibility:[149]



If the reaction is carried out with ketone labeled in the C=O group with ^{14}C, the first pathway predicts that the product will contain all the ^{14}C in the C=O carbon, while in the second pathway the label will be in the α carbon (demonstrating migration of oxygen). The results of such experiments[150] have shown that in some cases only the C=O carbon was labeled, in other cases only the a carbon, while in still others both carbons bore the label, indicating that in these cases both pathways were in operation. With α-hydroxy aldehydes and ketones, the process may stop after only one migration (this is called the α-*ketol* rearrangement).

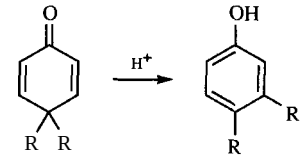


The α-ketol rearrangement can also be brought about by base catalysis, but only if the alcohol is tertiary, since if R^1 or R^2 = hydrogen, enolization of the substrate is more favored than rearrangement.

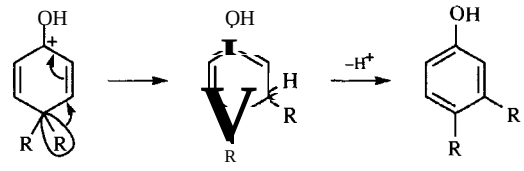


18-5 *The Dienone–Phenol Rearrangement*

2/*C* → 5/*O*-HYDRO, 1/*C* → 2/*C*-ALKYL-*BIS*-MIGRATION

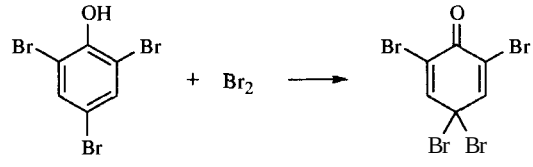


Compounds in which a cyclohexadienone has two alkyl groups in the 4 position undergo, on acid treatment,[151] 1,2 migration of one of these groups:



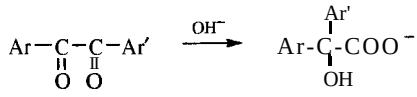
56 57

The driving force in the overall reaction (the *dienone–phenol rearrangement)* is of course creation of an aromatic system.[152] It may be noted that 56 and 57 are arenium ions (p. 676), the same as those generated by attack of an electrophile on a phenol.[153] Sometimes, in the reaction of a phenol with an electrophile, a kind of reverse rearrangement (called the *phenol–dienone rearrangement)* takes place, though without an actual migration.[154] An example is

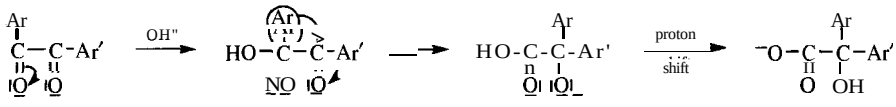


18-6 *The Benzil-Benzilic Acid Rearrangement*

1/*O*-HYDRO, 3/OXIDO-(1/ → 2/ARYL)-*MIGRO*- ADDITION



When treated with base, a-diketones rearrange to give the salts of a-hydroxy acids, a reaction known as the *benzil–benzilicacid rearrangement* (benzil is PhCOCOPh; benzilic acid is $Ph_2COHCOOH$).[155] A rhodium catalyzed version of this reaction has also been reported.[156] Though the reaction is usually illustrated with aryl groups, it can also be applied to aliphatic diketones[157] and to a-keto aldehydes. The use of alkoxide ion instead of OH^- gives the corresponding ester directly,[158] though alkoxide ions that are readily oxidized (such as OEt^- or $OCHMe_2^-$) are not useful here, since they reduce the benzil to a benzoin. The mechanism is similar to the rearrangements in 18-1-18-4, but there is a difference: The migrating group does not move to a carbon with an open sextet. The carbon makes room for the migrating group by releasing a pair of *n* electrons from the C=O bond to the oxygen. The first step is attack of the base at the carbonyl group, the same as the first step of the tetrahedral mechanism of nucleophilic substitution (p. 424) and of many additions to the C=O bond (Chapter 16):

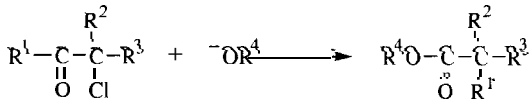


The mechanism has been intensely studied,[155] and there is much evidence for it.[159] The reaction is irreversible.

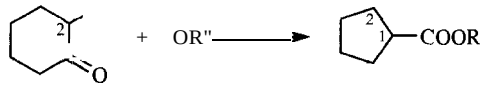
OS I, 89.

18-7 *The Favorskii Rearrangement*

2/ALKOXY-DE-CHLORO(2/→ 1/ALKYL)-*MIGRO*-SUBSTITUTION

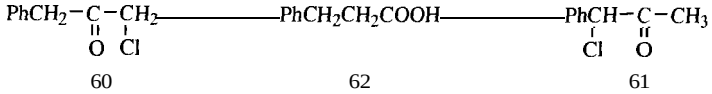


The reaction of a-halo ketones (chloro, bromo, or iodo) with alkoxide ions[160] to give rearranged esters is called the *Favorskii rearrangement*.[161] The use of hydroxide ions or amines as bases leads to the free carboxylic acid (salt) or amide, respectively, instead of the ester. Cyclic a-halo ketones give ring contraction, as in the conversion of 58 to 59.



58 59

The reaction has also been carried out on a-hydroxy ketones[162] and on a,P-epoxy ketones, which give P-hydroxy acids.[163] The fact that an epoxide gives a reaction analogous to a halide indicates that the oxygen and halogen are leaving groups in a nucleophilic substitution step.

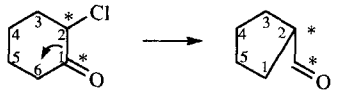


60 62 61

Through the years, the mechanism[164] of the Favorskii rearrangement has been the subject of much investigation; at least five different mechanisms have been proposed. However, the finding[165] that 60 and 61 *both* give 62 (this behavior is typical) shows that any mechanism where the halogen leaves and R^1 takes its place is invalid, since in such a case 60 would be expected to give 62 (with $PhCH_2$ migrating), but 61 should give PhCHMeCOOH (with CH_3 migrating). That is, in the case of 61, it was PhCH that migrated and not methyl. Another important result was determined by radioactive labeling. Compound 58, in which C-1 and C-2 were equally labeled with ^{14}C, was converted to 59. The product was found to contain 50% of the label on the carbonyl carbon, 25% on C-1, and 25% on C-2.[166] Now the carbonyl carbon, which originally carried one-half of the radioactivity, still had this much, so the rearrangement did not directly affect *it.* However, if the C-6 carbon had migrated to C-2, the other half of the radioactivity would be only on C-1 of the product:

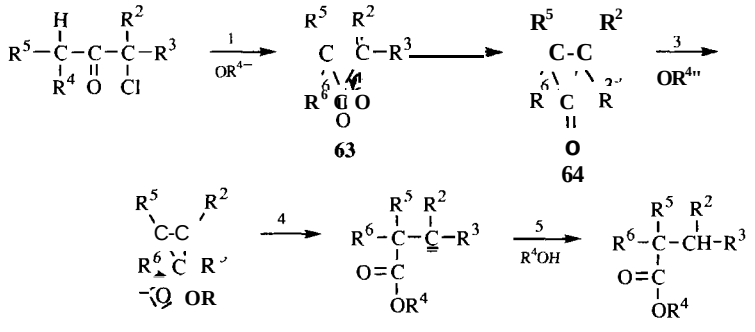
58

On the other hand, if the migration had gone the other way—if the C-2 carbon had migrated to C-6—then this half of the radioactivity would be found solely on C-2 of the product:



58

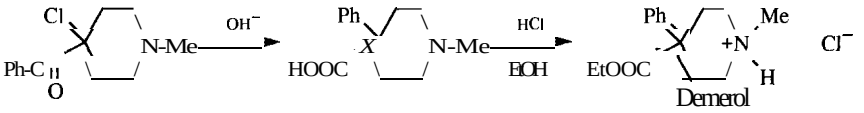
The fact that C-1 and C-2 were found to be equally labeled showed that *both migrations occurred,* with equal probability. Since C-2 and C-6 of 58 are not equivalent, this means that there must be a symmetrical intermediate.[167] The type of intermediate that best fits the circumstances is a cyclopropanone,[168] and the mechanism (for the general case) is formulated (replacing R^1 of our former symbolism with CHR^5R^6, since it is obvious that for this mechanism an α hydrogen is required on the *non-halogenated* side of the carbonyl):



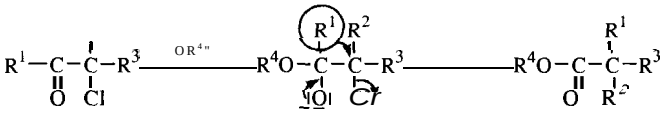
63 **64**

The intermediate corresponding to **64** in the case of 58 is a symmetrical compound, and the three-membered ring can be opened with equal probability on either side of the carbonyl, accounting for the results with ^{14}C. In the general case, **64** is not symmetrical and should open on the side that gives the more stable carbanion.[169] This accounts for the fact that **60** and **61** give the same product. The intermediate in both cases is **63,** which always opens to give the carbanion stabilized by resonance. The cyclopropanone intermediate (64) has been isolated in the case where $R^2=R^5=t$-Bu and $R^3=R^6=H$,[170] and it has also been trapped.[171] Also, cyclopropanones synthesized by other methods have been shown to give Favorskii products on treatment with NaOMe or other bases.[172]

The mechanism discussed is in accord with all the facts when the halo ketone contains an α hydrogen on the other side of the carbonyl group. However, ketones that do not have a hydrogen there also rearrange to give the same type of product. This is usually called the *quasi-Favorskii rearrangement.* An example is found in the preparation of Demerol:[173]



The quasi-Favorskii rearrangement obviously cannot take place by the cyclopropanone mechanism. The mechanism that is generally accepted (called the *semibenzilic mechanism*[174]) is a base-catalyzed pinacol rearrangement-type mechanism

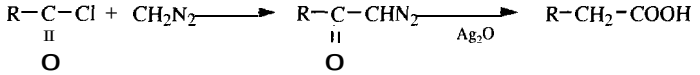


similar to that of **18-6.** This mechanism requires inversion at the migration terminus and this has been found.[175] It has been shown that even where there *is* an appropriately situated a hydrogen, the semibenzilic mechanism may still operate.[176]

An interesting analog of the Favorskii rearrangement treats a ketone such as 4-*tert*-butylcyclohexanone, without an α-halogen with $Tl(NO_3)_3$ to give *3-tert*-butylcyclopentane-1 -carboxylic acid.[177]

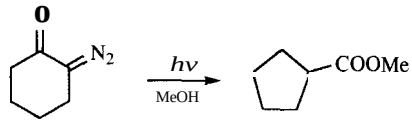
OS IV, 594; VI, 368, 711.

18-8 *The Arndt-Eistert Synthesis*

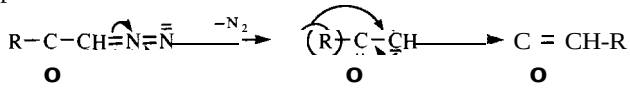


In the *Arndt-Eistert synthesis* an acyl halide is converted to a carboxylic acid with one additional carbon.[178] The first step of this process is Reaction **10-122.** The actual rearrangement occurs in the second step on treatment of the diazo ketone with water and silver oxide or with silver benzoate and triethylamine. This rearrangement is called the *Wolff rearrangement.*[179] It is the best method of increasing a carbon chain by one if a *carboxylic acid* is available (**10-111** and **16-34** begin with alkyl halides).

If an alcohol R'OH is used instead of water, the ester RCH_2COOR' is isolated directly.[180] Similarly, ammonia gives the amide. Other catalysts are sometimes used (e.g., colloidal platinum and copper), but occasionally the diazo ketone is simply heated or photolyzed in the presence of water, an alcohol, or ammonia, with no catalyst at all.[181] The photolysis method[182] often gives better results than the silver catalysis method. Of course, diazo ketones prepared in any other way also give the rearrangement.[183] The reaction is of wide scope. The R group may be alkyl or aryl and may contain many functional groups including unsaturation, but not including groups acidic enough to react with CH_2N_2 or diazo ketones (e.g., 10-5 and 10-28). Sometimes the reaction is performed with other diazoalkanes (that is, $R'CHN_2$) to give RCHR'COOH. The reaction has often been used for ring contraction of cyclic diazo ketones,[184] for example, [185]

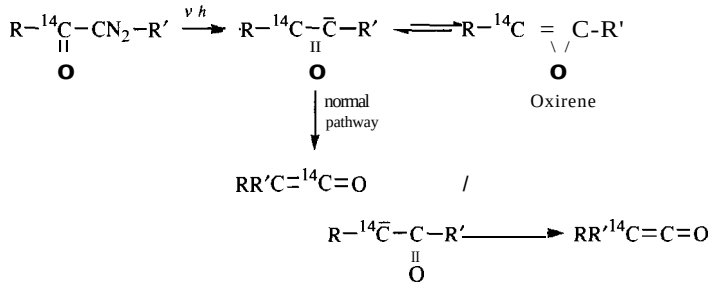


The mechanism is generally regarded as involving formation of a carbene. It is the divalent carbon that has the open sextet and to which the migrating group brings its electron pair:

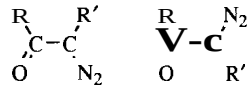


The actual product of the reaction is thus the ketene, which then reacts with water (15-3), an alcohol (15-5), or ammonia or an amine (15-8). Particularly stable ketenes (e.g., $Ph_2C{=}C{=}O$) have been isolated and others have been trapped in other ways (e.g., as β-lactams,[186] 16-64). The purpose of the catalyst is not well understood, though many suggestions have been made. This mechanism is strictly analogous to that of the Curtius rearrangement (18-14). Although the mechanism as shown above involves a free carbene and there is much evidence to support this,[187] it is also possible that at least in some cases the two steps are concerted and a free carbene is absent.

When the Wolff rearrangement is carried out photochemically, the mechanism is basically the same,[182] but another pathway can intervene. Some of the ketocarbene originally formed can undergo a carbene-carbene rearrangement, through an oxirene intermediate.[188] This was shown by ^{14}C labeling experiments, where diazo



ketones labeled in the carbonyl group gave rise to ketenes that bore the label at both C=C carbons.[189] In general, the smallest degree of scrambling (and thus of the oxirene pathway) was found when R' = H. An intermediate believed to be an oxirene has been detected by laser spectroscopy.[190] The oxirene pathway is not found in the thermal Wolff rearrangement. It is likely that an excited singlet state of the carbene is necessary for the oxirene pathway to intervene.[191] In the photochemical process, ketocarbene intermediates, in the triplet state, have been isolated in an Ar matrix at 10-15 K, where they have been identified by UV-visible, IR, and ESR spectra.[192] These intermediates went on to give the rearrangement via the normal pathway, with no evidence for oxirene intermediates.



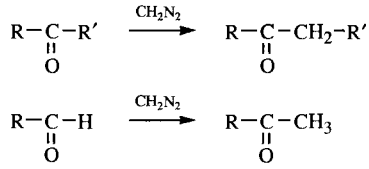
s-(Z) s-(*E*)

The diazo ketone can exist in two conformations, called *s-(E)* and *s-(Z).* Studies have shown that Wolff rearrangement takes place preferentially from the *s-(Z)* conformation.[193]

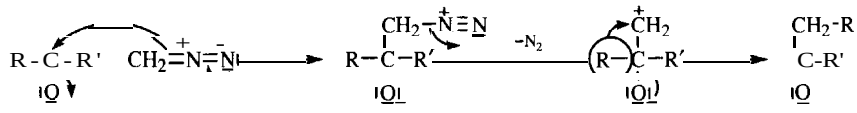
OS **III,** 356; VI, 613, 840.

18-9 *Homologation of Aldehydes and Ketones*

METHYLENE-INSERTION



Aldehydes and ketones[194] can be converted to their homologs with diazomethane.[195] Several other reagents[196] are also effective, including Me_3SiI, and then silica gel,[197] $LiCH(B{-}OCH_2CH_2O{-})_2$.[198] With the diazomethane reaction, formation of an epoxide **(16-61)** is a side reaction. Although this reaction appears superficially to be similar to the insertion of carbenes into C–H bonds, **12-19** (and IUPAC names it as an insertion), the mechanism is quite different. This is a true rearrangement and no free carbene is involved. The first step is an addition to the C=O bond:

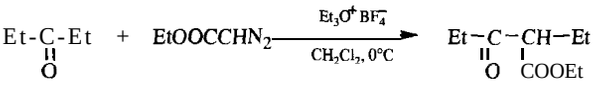


65

The betaine (65) can sometimes be isolated. As shown in **16-61, 65** can also go to the epoxide. The evidence for this mechanism is summarized in the review by

Gutsche.[195] It may be noted that this mechanism is essentially the same as in the apparent "insertions" of oxygen **(18-19)** and nitrogen **(18-16)** into ketones.

Aldehydes give fairly good yields of methyl ketones; that is, hydrogen migrates in preference to alkyl. The most abundant side product is not the homologous aldehyde, but the epoxide. However, the yield of aldehyde at the expense of methyl ketone can be increased by the addition of methanol. If the aldehyde contains electron-withdrawing groups, the yield of epoxides is increased and the ketone is formed in smaller amounts, if at all. Ketones give poorer yields of homologous ketones. Epoxides are usually the predominant product here, especially when one or both R groups contain an electron-withdrawing group. The yield of ketones also decreases with increasing length of the chain. The use of a Lewis acid increases the yield of ketone.[199] Cyclic ketones,[200] three membered[201] and larger, behave particularly well and give good yields of ketones with the ring expanded by one.[202] Aliphatic diazo compounds (RCHN2 and R_2CN_2) are sometimes used instead of diazomethane, with the expected results.[203] Ethyl diazoacetate can be used analogously, in the presence of a Lewis acid or of triethyloxonium fluoroborate,[204] for example,



When unsymmetrical ketones were used in this reaction (with BF_3 as catalyst), the less highly substituted carbon preferentially migrated.[205] The reaction can be made regioselective by applying this method to the α-halo ketone, in which case only the other carbon migrates.[206] The ethyl diazoacetate procedure has also been applied to the acetals or ketals of α,β-unsaturated aldehydes and ketones.[207]

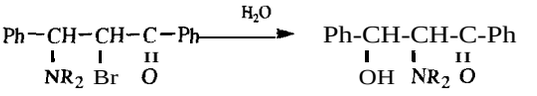
Bicyclic ketones can be expanded to form monocyclic ketones in the presence of certain reagents. Treatment of a bicyclo[4.1.0]hexan-4-one derivative with SmI_2 led to a cyclohexanone.[208] The SmI_2 compound also converts α-halomethyl cyclic ketones to the next larger ring ketone[209] and cyclic ketones to the next larger ring ketone in the presence of CH_2I_2.[210] α-Chloro-α-3-iodopropylcyclobutanones were converted to cycloheptanones using radical conditions (Bu_3SnH/AIBN).[211]

OS IV, 225, 780. For homologation of carboxyl acid derivatives, see OS IX, 426

B. *Carbon-to-Carbon Migrations of Other Groups*

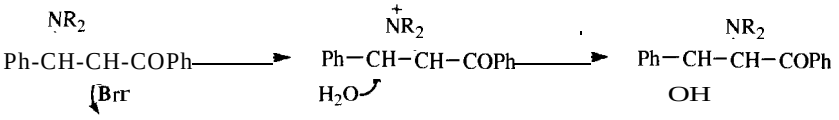
18-10 *Migrations of Halogen, Hydroxyl, Amino, and so on*

HYDROXY-DE-BROMO-*CINE*-SUBSTITUTION, AND SO ON



When a nucleophilic substitution is carried out on a substrate that has a neighboring group (p, 404) on the adjacent carbon, if the cyclic intermediate is opened on the

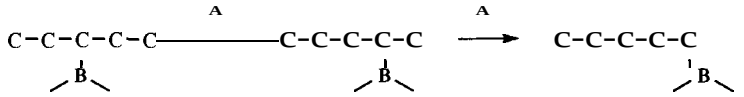
opposite side, the result is migration of the neighboring group. In the example shown above (NR_2 = morpholino),[212] the reaction took place as follows:



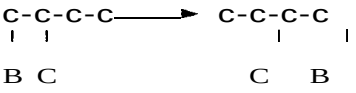
Sulfonate esters and halides can also migrate in this reaction.[213] α-Halo and α-acyloxy epoxides undergo ready rearrangement to α-halo and α-acyloxy ketones, respectively.[214] These substrates are very prone to rearrange, and often do so on standing without a catalyst, though in some cases an acid catalyst is necessary. The reaction is essentially the same as the rearrangement of epoxides shown in 18-2, except that in this case halogen or acyloxy is the migrating group (as shown above; however, it is also possible for one of the R groups—alkyl, aryl, or hydrogen—to migrate instead, and mixtures are sometimes obtained).

18-11 *Migration of Boron*

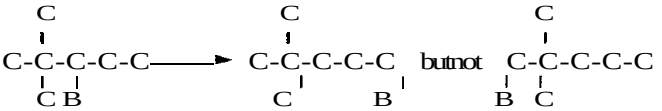
HYDRO, DIALKYLBORO-INTERCHANGE, AND SO ON



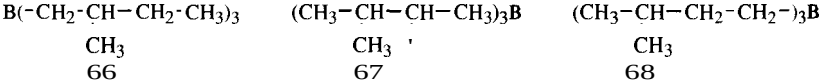
When a nonterminal borane is heated at temperatures ranging from 100 to 200°C, the boron moves toward the end of the chain.[215] The reaction is catalyzed by small amounts of borane or other species containing B—H bonds. The boron can move past a branch, for example,



but not past a double branch, for example,



The reaction is an equilibrium: 66, 67, and 68 each gave a mixture containing about 40% 66, 1% 67, and 59% 68. The migration can go quite a long distance. Thus $(C_{11}H_{23}CHC_{11}H_{23})_3B$ was completely converted to $(C_{23}H_{47})_3B$, involving a migration of 11 positions.[216] If the boron is on a cycloalkyl ring, it can move around

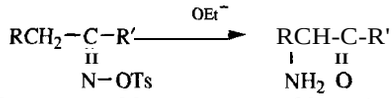


the ring; if any alkyl chain is also on the ring, the boron may move from the ring to the chain, ending up at the end of the chain.[217] The reaction is useful for the migra-

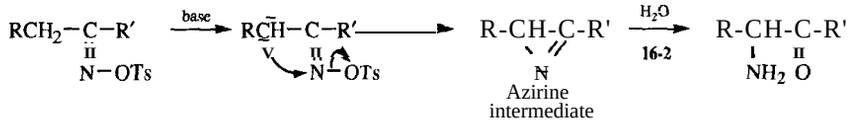
tion of double bonds in a controlled way (see 12-2). The mechanism may involve a π complex, at least partially.[218]

18-12 *The Neber Rearrangement*

NEBER OXIME TOSYLATE-AMINO KETONE REARRANGEMENT



α-Amino ketones can be prepared by treatment of ketoxime tosylates with a base such as ethoxide ion or pyridine.[219] This is called the *Neber rearrangement.* The R group is usually aryl, though the reaction has been carried out with R = alkyl or hydrogen. The R' group may be alkyl or aryl but not hydrogen. The Beckmann rearrangement **(18-17)** and the abnormal Beckmann reaction (elimination to the nitrile, **17-31)** may be side reactions, though these generally occur in acid media. A similar rearrangement is given by N,N-dichloroamines of the type $RCH_2CH(NCl_2)R'$, where the product is also $RCH(NH_2)COR'$.[220] The mechanism of the Neber rearrangement is as follows:[221]

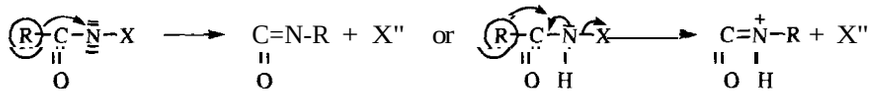


The best evidence for this mechanism is that the azirine intermediate has been isolated.[222] In contrast to the Beckmann rearrangement, this one is sterically indiscriminate:[223] Both a syn and an anti ketoxime give the same product. The mechanism as shown above consists of three steps. However, it is possible that the first two steps are concerted, and it is also possible that what is shown as the second step is actually two steps: loss of OTs to give a nitrene, and formation of the azirine. In the case of the dichloroamines, HC1 is first lost to give $RCH_2C(=NCl)R'$, which then behaves analogously.[224] N-Chloroimines prepared in other ways also give the reaction.[225]

OS V, 909; **VII,** 149.

C. *Carbon-to-Nitrogen Migrations of R and Ar*

The reactions in this group are nucleophilic migrations from a carbon to a nitrogen atom. In each case, the nitrogen atom either has six electrons in its outer shell (and thus invites the migration of a group carrying an electron pair) or else loses a nucleofuge concurrently with the migration (p. 1379). Reactions **18-13-18-16** are used to prepare amines from acid derivatives. Reactions **18-16** and **18-17** are used to prepare amines from ketones. The mechanisms of **18-13, 18-14, 18-15,** and **18-16** (with carboxylic acids) are very similar and follow one of two patterns:



Some of the evidence[226] is (1) configuration is retained in R (p. 1380); (2) the kinetics are first order; (3) intramolecular rearrangement is shown by labeling; and (4) no rearrangement occurs *within* the migrating group (e.g., a neopentyl group on the carbon of the starting material is still a neopentyl group on the nitrogen of the product).

In many cases it is not certain whether the nucleofuge X is lost first, creating an intermediate nitrene[227] or nitrenium ion, or whether migration and loss of the nucleofuge are simultaneous, as shown above.[228] It is likely that both possibilities can exist, depending on the substrate and reaction conditions.

18-13 *The Hofmann Rearrangement*

BISHYDROGEN-(2/→ 1/*N*-ALKYL)-*MIGRO*-DETACHMENT
(FORMATION OF ISOCYANATE)

$$RCONH_2 + NaOBr \longrightarrow R{-}N{=}C{=}O \xrightarrow[16\text{-}2]{\text{hydrolysis}} RNH_2$$

In the *Hofmann rearrangement*, an unsubstituted amide is treated with sodium hypobromite (or sodium hydroxide and bromine, which is essentially the same thing) to give a primary amine that has one carbon fewer than the starting amide.[229] The actual product is the isocyanate, but this compound is seldom isolated[230] since it is usually hydrolyzed under the reaction conditions. The R group may be alkyl or aryl, but if it is an alkyl group of more than about six or seven carbons, low yields are obtained unless Br_2 and NaOMe are used instead of Br_2 and NaOH.[231] Another modification uses NBS/NaOMe.[232] Under these conditions the product of addition to the isocyanate is the carbamate RNHCOOMe (16-7), which is easily isolated or can be hydrolyzed to the amine. Side reactions when NaOH is the base are formation of ureas (RNHCONHR) and acylureas (RCONHCONHR) by addition, respectively, of RNH_2 and $RCONH_2$ to RNCO (16-16). If acylureas are desired, they can be made the main products by using only one half the usual quantities of Br_2 and NaOH. Another side product, though only from primary R, is the nitrile derived from oxidation of RNH2 (19-5). Imides react to give amino acids (e.g., phthalimide gives *o*-aminobenzoic acid). α-Hydroxy and a-halo amides give aldehydes and ketones by way of the unstable a-hydroxy- or α-haloamines. However, a side product with an a-halo amide is a *gem*-dihalide. Ureas analogously give hydrazines.

The mechanism follows the pattern outlined on page 1410.

$$R{-}\underset{\underset{O}{\|}}{C}{-}NH_2 + Br_2 \longrightarrow R{-}\underset{\underset{O}{\|}}{C}{-}NH{-}Br \xrightarrow{OH^-} \underset{\underset{O}{\|}}{R{-}C{-}\bar{N}{-}Br} \longrightarrow C{=}\bar{N}{-}R$$

69

The first step is an example of 12-52 and intermediate N-halo amides (69) have been isolated. In the second step, 69 lose a proton to the base. Compound 69 are acidic because of the presence of two electron-withdrawing groups (acyl and halo) on the nitrogen. It is possible that the third step is actually two steps: loss of bromide to

form a nitrene, followed by the actual migration, but most of the available evidence favors the concerted reaction.[233] A similar reaction can be effected by the treatment of amides with lead tetraacetate.[234] Among other reagents that convert $RCONH_2$ to RNH_2 (R = alkyl, but not aryl) are phenyliodosyl bis(trifluoroacetate), $PhI(O\text{-}COCF_3)_2$[235] and hydroxy(tosyloxy)iodobenzene, PhI(OH)OTs.[236] A mixture of NBS, $Hg(OAc)_2$, and R'OH is one of several reagent mixtures that convert an amide ($RCONH_2$) to the carbamate (RNHCOOR') (R = primary, secondary, or tertiary alkyl or aryl) in high yield.[237] A mixture of NBS and DBU in methanol gives the carbamate,[238] as does electrolysis in methanol.[239]

OS **II,** 19, 44, 462; **IV,** 45; **VIII,** 26, 132.

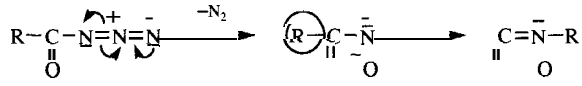
18-14 *The Curtius Rearrangement*

DINITROGEN-(2/→ 1/*N*-ALKYL)-*MIGRO*-DETACHMENT

$$RCON_3 \xrightarrow{\Delta} R{-}N{=}C{=}O$$

The *Curtius rearrangement* involves the pyrolysis of acyl azides to yield isocyanates.[240] The reaction gives good yields of isocyanates, since no water is present to hydrolyze them to the amine. Of course, they can be subsequently hydrolyzed, and indeed the reaction *can* be carried out in water or alcohol, in which case the products are amines, carbamates, or acylureas, as in **18-13**.[241] This is a very general reaction and can be applied to almost any carboxylic acid: aliphatic, aromatic, alicyclic, heterocyclic, unsaturated, and containing many functional groups. Acyl azides can be prepared as in **10-65** or by treatment of acylhydrazines (hydrazides) with nitrous acid (analogous to **12-48).** The Curtius rearrangement is catalyzed by Lewis or protic acids, but these are usually not necessary for good results.

The mechanism is similar to that in **18-13:**



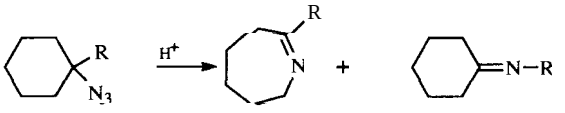
Also note the exact analogy between this reaction and **18-8.** However, in this case, there is no evidence for a free nitrene and it is probable that the steps are concerted.[242]

Alkyl azides can be similarly pyrolyzed to give imines, in an analogous reaction:

$$R_3CN_3 \xrightarrow{\Delta} R_2C{=}NR$$

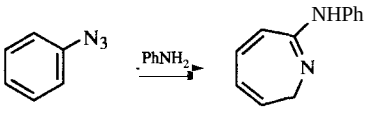
The R groups may be alkyl, aryl, or hydrogen, though if hydrogen migrates, the product is the unstable $R_2C{=}NH$. The mechanism is essentially the same as that of the Curtius rearrangement. However, in pyrolysis of tertiary alkyl azides, there is evidence that free alkyl nitrenes are intermediates.[244] The reaction can also be carried out with acid catalysis, in which case lower temperatures can be used, though

the acid may hydrolyze the imine (16-2). Cycloalkyl azides give ring expansion.[245]



~80% ~20%

Aryl azides also give ring expansion on heating, for example,[246]



A

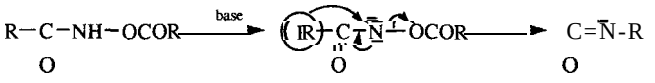
OS HI, 846; IV, 819; V, 273; VI, 95, 910. Also see OS VI, 210.

18-15 *The Lossen Rearrangement*

HYDRO,ACETOXY-(2/⟶1*N*-ALKYL)-*MIGRO*-DETACHMENT

$$R-\underset{\underset{O}{\|}}{C}-NHOCOR \xrightarrow{OH^-} R-N=C=O \xrightarrow{H_2O} RNH_2$$

The O-acyl derivatives of hydroxamic acids[247] give isocyanates when treated with bases or sometimes even just on heating, in a reaction known as the *Lossen rearrangement.*[248] The mechanism is similar to that of **18-13** and **18-14:**



In a similar reaction, aromatic acyl halides are converted to amines in one laboratory step by treatment with hydroxylamine-O-sulfonic acid.[249]

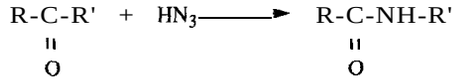
$$Ar-\underset{\underset{O}{\|}}{C}-Cl \xrightarrow{NH_2OSO_2OH} \left[Ar-\underset{\underset{O}{\|}}{C}-NH-OSO_2OH\right] \longrightarrow ArNH_2$$

18-16 *The Schmidt Reaction*

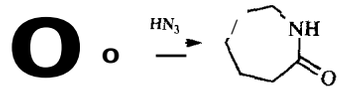
$$RCOOH + HN_3 \xrightarrow{H^+} R-N=C=O \xrightarrow{H_2O} RNH_2$$

There are actually three reactions called by the name *Schmidt reaction,* involving the addition of hydrazoic acid to carboxylic acids, aldehydes and ketones, and alcohols and alkenes.[250] The most common is the reaction with carboxylic acids, illustrated above.[251] Sulfuric acid is the most common catalyst, but Lewis acids have also been used. Good results are obtained for aliphatic R, especially for long chains. When R is aryl, the yields are variable, being best for sterically hindered compounds like mesitoic acid. This method has the advantage over **18-13** and **18-14** that it is just one laboratory step from the acid to the amine, but conditions are more drastic.[252] Under the acid conditions employed, the isocyanate is virtually never isolated.

The reaction between a ketone and hydrazoic acid is a method for "insertion" of NH between the carbonyl group and one R group, converting a ketone into an amide.[253]



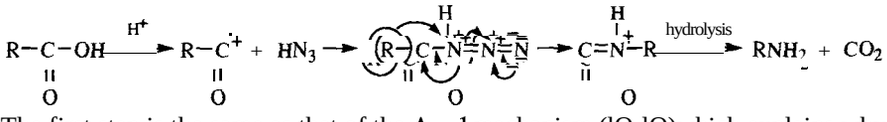
Either or both of the R groups may be aryl. In general, dialkyl ketones and cyclic ketones react more rapidly than alkyl aryl ketones, and these more rapidly than diaryl ketones. The latter require sulfuric acid and do not react in concentrated HC1, which is strong enough for dialkyl ketones. Dialkyl and cyclic ketones react sufficiently faster than diaryl or aryl alkyl ketones or carboxylic acids or alcohols that these functions may be present in the same molecule without interference. Cyclic ketones give lactams:[254]



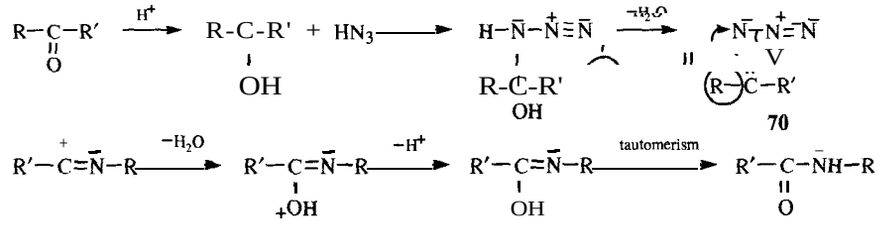
With alkyl aryl ketones, it is the aryl group that generally migrates to the nitrogen, except when the alkyl group is bulky.[255] The reaction has been applied to a few aldehydes, but rarely. With aldehydes the product is usually the nitrile (16-21). Even with ketones, conversion to the nitrile is often a side reaction, especially with the type of ketone that gives 17-31. A useful variation of the Schmidt reaction treats a cyclic ketone with an alkyl azide (RN_3) in the presence of $TiCl_4$, generating a lactam.[256] Another variation treats a silyl enol ether of a cyclic ketone with $TMSN_3$ and photolyzes the product with UV light to give a lactam.[257]

Alcohols and alkenes react with HN_3 to give alkyl azides,[258] which in the course of reaction rearrange in the same way as discussed in reaction **18-14**.[243] The Mitsunobu reaction (10-23) can be used to convert alcohols to alkyl azides, and an alternative reagent for azides, $(PhO)_2PON_3$, to the Mitsunobu is now available.[259]

There is evidence that the mechanism with carboxylic acids is similar to that of 18-14, except that it is the protonated azide that undergoes the rearrangement:[260]



The first step is the same as that of the $A_{AC}1$ mechanism (lO-lO)which explains why good results are obtained with hindered substrates. The mechanism with ketones is[261]

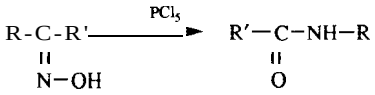


The intermediates (7) have been independently generated in aqueous solution.[262] Note the similarity of this mechanism to those of "insertion" of CH_2 **(18-9)** and of O **(18-19).** The three reactions are essentially analogous, both in products and in mechanism.[263] Also note the similarity of the latter part of this mechanism to that of the Beckmann rearrangement **(18-17).**

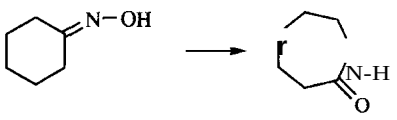
OS **V,** 408; **VI,** 368; **VII,** 254; **75,** 31. See also OS V, 623.

18-17 *The Beckmann Rearrangement*

BECKMANN OXIME-AMIDE REARRANGEMENT



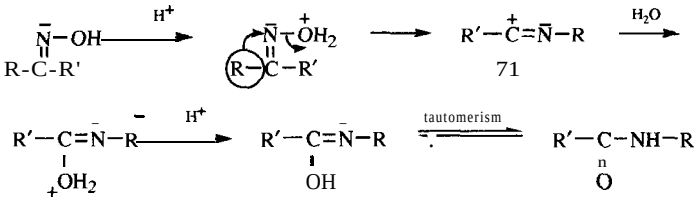
When oximes are treated with PCl_5 or a number of other reagents, they rearrange to substituted amides in a reaction called the *Beckmann rearrangement.*[264] Among other reagents used have been concentrated H_2SO_4, formic acid, liquid SO_2, $SOCl_2$,[265] silica gel,[266] HCl—HOAc—Ac_2O, $POCl_3$,[267] and polyphosphoric acid.[268] Heating an oxime of a cyclic ketone, *neat,* with $AlCl_3$ also leads to the lactam.[269] Treatment of a cyclic ketone with NH_2OSO_3H on silica gel followed by microwave irradiation also gives the lactam.[270] Microwave irradiation of an oxime on Montmorillonite K10 clay gives the amide.[271] The group that migrates is generally the one anti to the hydroxyl, and this is often used as a method of determining the configuration of the oxime. However, it is not unequivocal. It is known that with some oximes the syn group migrates and that with others, especially where R and R' are both alkyl, mixtures of the two possible amides are obtained. However, this behavior does not necessarily mean that the syn group actually undergoes migration. In most cases, the oxime undergoes isomerization under the reaction conditions *before* migration takes place.[272] The scope of the reaction is quite broad. Both R and R' may be alkyl, aryl, or hydrogen. However, hydrogen very seldom *migrates,* so the reaction is not generally a means of converting aldoximes to unsubstituted amides $RCONH_2$. This conversion can be accomplished, though, by treatment of the aldoxime with nickel acetate under neutral conditions[273] or by heating the aldoxime for 60 h at 100°C after it has been adsorbed onto silica gel.[274] As in the case of the Schmidt rearrangement, when the oxime is derived from an alkyl aryl ketone, it is generally the aryl group that preferentially migrates. The oximes of cyclic ketones give ring enlargement,[275] for example,



Not only do oximes undergo the Beckmann rearrangement, but so also do esters of oximes with many acids, organic and inorganic. A side reaction with many substrates is the formation of nitriles (the "abnormal" Beckmann rearrangement, **17-31).** Cyclic ketones can be converted directly to lactams in one laboratory step by

treatment with NH_2OSO_2OH and formic acid **(16-19** takes place first, then the Beckmann rearrangement).[276]

In the first step of the mechanism, the OH group is converted by the reagent to a better leaving group (e.g., proton acids convert it to OH_2^+). After that, the mechanism[277] follows a course analogous to that for the Schmidt reaction of ketones (18-**16)** from the formation of **71** on:[278]



The other reagents convert OH to an ester leaving group (e.g., $OPCl_4$ from PCl_5 and OSO_2OH from concentrated H_2SO_4[279]). Alternatively, the attack on **71** can be by the leaving group, if different from H_2O. Intermediates of the form **71** have been detected by NMR and UV spectroscopy.[280] The rearrangement has also been found to take place by a different mechanism, involving formation of a nitrile by fragmentation, and then addition by a Ritter reaction (16-56).[281] Beckmann rearrangements have also been carried out photochemically.[282]

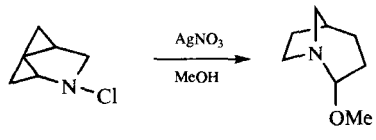
If the rearrangement of oxime sulfonates is induced by organoaluminum reagents,[283] the intermediate (71) is captured by the nucleophile originally attached to the Al. By this means an oxime can be converted to an imine, an imino thioether (R–N=C–SR), or an imino nitrile (R–N=C–CN).[284] In the last case, the nucleophile comes from added trimethylsilyl cyanide. The imine-producing reaction can also be accomplished with a Grignard reagent in benzene or toluene.[285]

In a related reaction, treatment of spirocyclic oxaziridines with MnCl(TPP), where TPP = *meso*-tetraphenylporphyrinate (2—),[286] or photolysis[287] leads to a lactam.

OS **II,** 76, 371; **VIII,** 568.

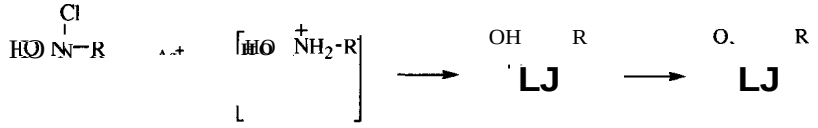
18-18 *Stieglitz and Related Rearrangements*

METHOXY-DE-*N*-CHLORO-(2/ → 1/*N*-ALKYL)-*MIGRO*-SUBSTITUTION, AND SO ON



Besides the reactions discussed at **18-13-18-17,** a number of other rearrangements are known in which an alkyl group migrates from C to N. Certain bicyclic N-haloamines, for example, *N*-chloro-2-azabicyclo[2.2.2]octane (above), undergo rearrangement when solvolyzed in the presence of silver nitrate.[288] This reaction is similar to the Wagner–Meerwein rearrangement **(18-1)** and is initiated by the silver-catalyzed departure of the chloride ion.[289] Similar reactions have been used for ring

expansions and contractions, analogous to those discussed for Reaction **18-3**.[290] An example is the conversion of 1-(*N*-chloroamino)cyclopropanols to β-lactams.[291]



The name *Stieglitz rearrangement* is generally applied to the rearrangements of trityl N-haloamines and

$$Ar_3CNHX \xrightarrow{\text{base}} Ar_2C{=}NAr$$

$$Ar_3CNHOH \xrightarrow{PCl_5} Ar_2C{=}NAr$$

hydroxylamines. These reactions are similar to the rearrangements of alkyl azides (18-14), and the name Stieglitz rearrangement is also given to the rearrangement of trityl azides. Another similar reaction is the rearrangement undergone by tritylamines when treated with lead tetraacetate:[292]

$$Ar_3CNH_2 \xrightarrow{Pb(OAc)_4} Ar_2C{=}NAr$$

D. *Carbon-to-Oxygen Migrations of R and Ar*

18-19 *The Baeyer–Villiger Rearrangement*

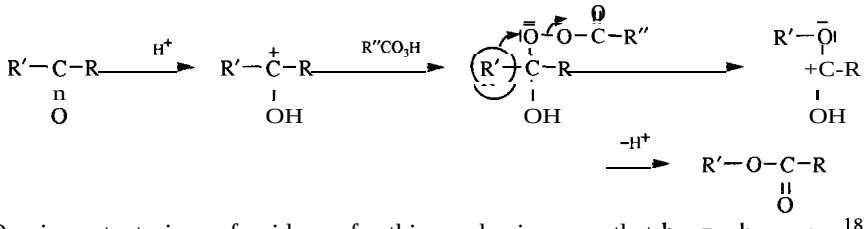
OXY-INSERTION

$$R\text{-}\underset{\underset{O}{\|}}{C}\text{-}R' + Ph\text{-}\underset{\underset{O}{\|}}{C}\text{-}OOH \longrightarrow R\text{-}\underset{\underset{O}{\|}}{C}\text{-}OR'$$

The treatment of ketones with peroxyacids such as peroxybenzoic or peroxyacetic acid, or with other peroxy compounds in the presence of acid catalysts, gives carboxylic esters by "insertion" of oxygen.[293] The reaction is called the *Baeyer-Villiger rearrangement.*[294] A particularly good reagent is peroxytrifluoroacetic acid. Reactions with this reagent are rapid and clean, giving high yields of product, though it is often necessary to add a buffer such as Na_2HPO_4 to prevent transesterification of the product with trifluoroacetic acid. The reaction is often applied to cyclic ketones to give lactones.[295] Enantioselective synthesis of chiral lactones from achiral ketones has been achieved by the use of enzymes as catalysts[296] and other asymmetric reactions are known.[297] For acyclic compounds, R' must usually be secondary, tertiary, or vinylic, although primary R' has been rearranged with peroxytrifluoroacetic acid,[298] with BF_3–H_2O_2,[299] and with $K_2S_2O_8$–H_2SO_4.[300] For unsymmetrical ketones the approximate order of migration is tertiary alkyl > secondary alkyl, aryl > primary alkyl > methyl. Since the methyl group has a low migrating ability, the reaction provides a means of cleaving a methyl ketone R'COMe to produce an alcohol or phenol R'OH (by hydrolysis of the ester R'OCOMe). The migrating ability of aryl groups is increased by electron-donating and decreased by electron-withdrawing substituents.[301] Enolizable P-diketones do

not react. α-Diketones can be converted to anhydrides.[302] With aldehydes, migration of hydrogen gives the carboxylic acid, and this is a way of accomplishing 14-6. Migration of the other group would give formates, but this seldom happens, though aryl aldehydes have been converted to formates with H_2O_2 and a selenium compound[303] (see also the Dakin reaction in 19-11).

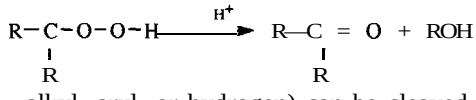
The mechanism[304] is similar to those of the analogous reactions with hydrazoic acid (18-16 with ketones) and diazomethane (18-8):



One important piece of evidence for this mechanism was that benzophenone-^{18}O gave ester entirely labeled in the carbonyl oxygen, with none in the alkoxyl oxygen.[305] Carbon-14 isotope-effect studies on acetophenones have shown that migration of aryl groups takes place in the rate-determining step,[306] demonstrating that migration of Ar is concerted with departure of OCOR".[307] (It is hardly likely that migration would be the slow step if the leaving group departed first to give an ion with a positive charge on an oxygen atom, which would be a highly unstable species.)

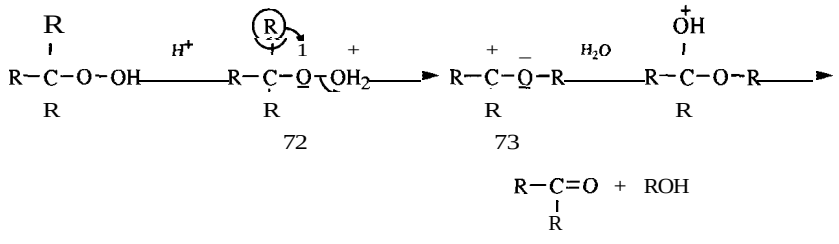
18-20 *Rearrangement of Hydroperoxides*

C-ALKYL-O-HYDROXY-ELIMINATION



Hydroperoxides (R=alkyl, aryl, or hydrogen) can be cleaved by proton or Lewis acids in a reaction whose principal step is a rearrangement.[308] The reaction has also been applied to peroxy esters (R3COOCOR'), but less often. When aryl and alkyl groups are both present, migration of aryl dominates. It is not necessary actually to prepare and isolate hydroperoxides. The reaction takes place when the lcohols are treated with H_2O_2 and acids. Migration of an alkyl group of a primary hydroperoxide provides a means for converting an alcohol to its next lower homolog (RCH_2-$OOH \rightarrow CH_2{=}O + ROH$).

The mechanism is as follows:[309]



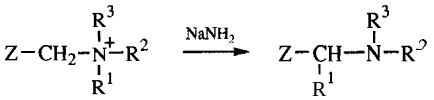
The last step is hydrolysis of the unstable hemiacetal. Alkoxycarbocation intermediates (73, R = alkyl) have been isolated in superacid solution[310] at low temperatures, and their structures proved by NMR.[311] The protonated hydroperoxides (72) could not be observed in these solutions, evidently reacting immediately on formation.

OS V, 818.

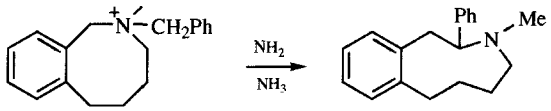
E. *Nitrogen-to-Carbon, Oxygen-to-Carbon, and Sulfur-to-Carbon Migration*

18-21 *The Stevens Rearrangement*

HYDRON-(2/*N*→ 1/ALKYL)-*MIGRO*-DETACHMENT



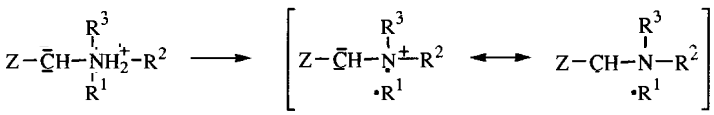
In the *Stevens rearrangement,* a quaternary ammonium salt containing an electron-withdrawing group Z on one of the carbons attached to the nitrogen is treated with a strong base (such as NaOR or $NaNH_2$) to give a rearranged tertiary amine. The Z group can be RCO, ROOC, phenyl, and so on.[312] The most common migrating groups are allylic, benzylic, benzhydryl, 3-phenylpropargyl, and phenacyl, though even methyl migrates to a sufficiently negative center.[313] When an allylic group migrates, it may or may not involve an allylic rearrangement within the migrating group (see **18-35),** depending on the substrate and reaction conditions. The reaction has been used for ring enlargement,[314] for example:



90%

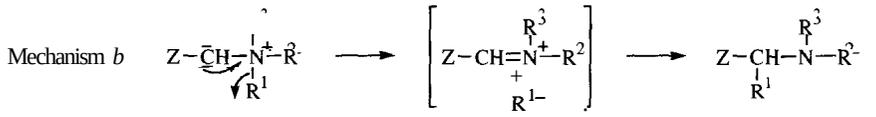
The mechanism has been the subject of much study.[315] That the rearrangement is intramolecular was shown by crossover experiments, by ^{14}C labeling,[316] and by the fact that retention of configuration is found at R^1.[317] The first step is loss of the acidic proton to give the ylid (74), which has been isolated.[318] The finding[319] that CIDNP spectra[320] could be obtained in many instances shows that in these cases the product is formed directly from a free-radical precursor. The following radical pair mechanism was proposed:[321]

Mechanism *a*



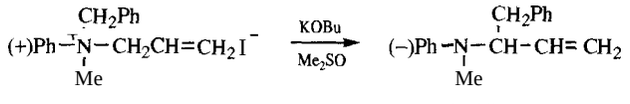
74 Solvent cage

The radicals do not drift apart because they are held together by the solvent cage. According to this mechanism, the radicals must recombine rapidly in order to account for the fact that R^1 does not racemize. Other evidence in favor of mechanism *a* is that in some cases small amounts of coupling products (R^1R^1) have been isolated,[322] which would be expected if some $\cdot R^1$ leaked from the solvent cage. However, not all the evidence is easily compatible with mechanism a.[323] It is possible that another mechanism *(b)* similar to mechanism *a,* but involving ion



74 Solvent cage

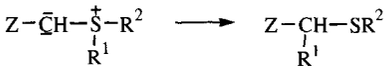
pairs in a solvent cage instead of radical pairs, operates in some cases. A third possible mechanism would be a concerted 1,2-shift,[324] but the orbital symmetry principle requires that this take place with inversion at R^1[325] (see p. 1440). Since the actual migration takes place with retention, it cannot, according to this argument, proceed by a concerted mechanism. However, in the case where the migrating group is allylic, a concerted mechanism can also operate **(18-35).** An interesting finding compatible with all three mechanisms is that optically active allylbenzylmethylphenylammonium iodide (asymmetric nitrogen, see p. 129) gave an optically active product:[326]



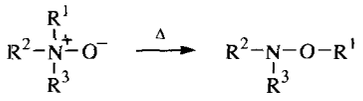
(15%)

The *Sommelet–Hauser rearrangement* competes when Z is an aryl group (see 13-22). *Hofmann elimination* competes when one of the R groups contains a (3 hydrogen atom **(17-6** and **17-7).**

Sulfur ylids containing a Z group give an analogous rearrangement, often also referred to as a Stevens rearrangement.[327] In this case too, there is much evidence



(including CIDNP) that a radical-pair cage mechanism is operating,[328] except that when the migrating group is allylic, the mechanism may be different (see **18-35).** Another reaction with a similar mechanism[329] is the *Meisenheimer rearrangement,*[330] in which certain tertiary amine oxides rearrange on heating to give



substituted hydroxylamines.[331] The migrating group R^1 is almost always allylic or benzilic.[332] The groups R^2 and R^3 may be alkyl or aryl, but if one of the R groups

contains a (3 hydrogen, Cope elimination **(17-8)** often competes. In a related reaction, when 2-methylpyridine N-oxides are treated with trifluoroacetic anhydride, the *Boekelheide reaction* occurs to give 2-hydroxymethylpyridines.[333]

Certain tertiary benzylic amines, when treated with BuLi, undergo a rearrangement analogous to the Wittig rearrangement **(18-22)** (e.g., $PhCH_2NPh_2 \rightarrow Ph_2CHNHPh$).[334] Only aryl groups migrate in this reaction.

Isocyanides, when heated in the gas phase or in nonpolar solvents, undergo a 1,2-intramolecular rearrangement to nitriles: RNC → RCN.[335] In polar solvents the mechanism is different.[336]

18-22 *The Wittig Rearrangement*

HYDRON-(2/*O*→ 1/ALKYL)-*MIGRO*-DETACHMENT

$$R{-}CH_2{-}O{-}R' \xrightarrow{R''Li} R{-}\underset{R'}{CH}{-}O^{-}\ Li^{+} + R''H$$

The rearrangement of ethers with alkyllithium reagents is called the *Wittig rearrangement* (not to be confused with the Wittig reaction, **16-47)** and is similar to **18-21**.[312] However, a stronger base is required (e.g., phenyllithium or sodium amide). The R and R' groups may be alkyl, aryl, or vinylic.[337] Also, one of the hydrogens may be replaced by an alkyl or aryl group, in which case the product is the salt of a tertiary alcohol. Migratory aptitudes here are allylic, benzylic > ethyl > methyl > phenyl.[338] The stereospecificity of the 1,2-Wittig rearrangement has been discussed.[339] The following radical-pair mechanism[340] (similar to mechanism *a* of **18-21)** is likely, after removal of the proton by the base. One of the radicals in the radical pair is a ketyl. Among the evidence for this mechanism is (1) the rearrangement is largely intramolecular; (2) migratory aptitudes are in the order of free-radical stabilities, not of carbanion stabilities[341] (which rules out an ion-pair mechanism similar to mechanism *b* of **18-21);** (3) aldehydes are obtained as side products;[342] (4) partial racemization of R' has been observed[343] (the remainder of the product retained its configuration); (5) crossover products have been detected;[344] and (6) when ketyl radicals and R • radicals from different precursors were brought together, similar products resulted.[345] However, there is evidence that at least in some cases the radical-pair mechanism accounts for only a portion of the product, and some kind of concerted mechanism can also take place.[346] Most of the above investigations were carried out with systems where R' is alkyl, but a radical-pair mechanism has also been suggested for the case where R' is aryl.[347] When R' is allylic a concerted mechanism can operate **(18-35).**

$$R{-}\underset{\cdot R'}{\overset{\cdot}{C}}H{-}\overset{\cdot}{O}{-}R' \longrightarrow \Big[\ R{-}\underset{\cdot R'}{\overset{\cdot}{C}}H{-}\overset{\cdot}{O}\ \longleftrightarrow\ R{-}\underset{\cdot R'}{\overset{\cdot}{C}}H{-}\overset{-}{O}\ \Big]_{J} \longrightarrow R{-}\underset{R'}{CH}{-}\overset{-}{O}$$

Solvent cage

When R is vinylic it is possible, by using a combination of an alkyllithium and *t*-BuOK, to get migration to the γ carbon (as well as to the a carbon), producing an

enolate that, on hydrolysis, gives an aldehyde:[348]

$$CH_2{=}CH{-}CH_2{-}OR' \longrightarrow R'CH_2{-}CH{=}CH{-}OLi \longrightarrow R'CH_2CH_2CHO$$

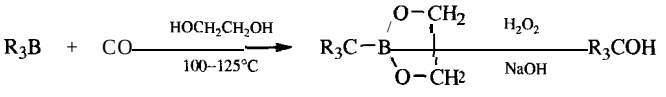
An aza-Wittig rearrangement is also known.[349]

There are no OS references, but see OS **VIII,** 501, for a related reaction.

F. *Boron-to-Carbon Migrations*[350]

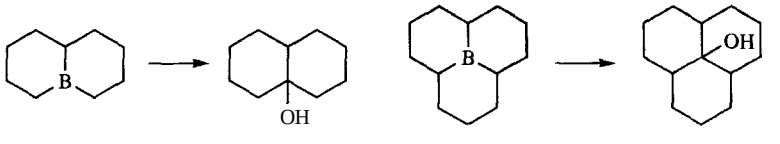
For another reaction involving boron-to-carbon migration, see **10-109.**

18-23 *Conversion of Boranes to Alcohols*



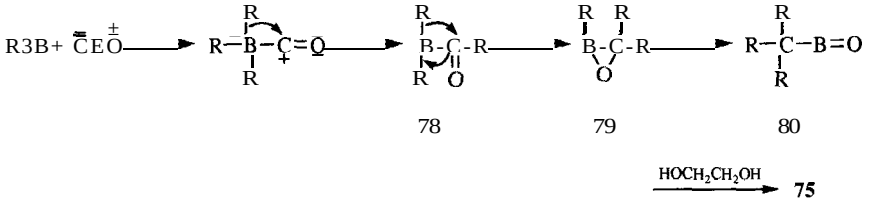
75

Trialkylboranes (which can be prepared from alkenes by **15-16)** react with carbon monoxide[351] at 100–125°C in the presence of ethylene glycol to give the 2-bora-l,3-dioxolanes (75), which are easily oxidized **(12-26)** to tertiary alcohols.[352] The R groups may be primary, secondary, or tertiary, and may be the same or different.[353] Yields are high and the reaction is quite useful, especially for the preparation of sterically hindered alcohols such as tricyclohexylcarbinol (76) and tri-2-norbornylcarbinol (77), which are difficult to prepare by **16-27.** Heterocycles in which boron is a ring atom react similarly (except that high CO pressures are required), and cyclic alcohols can be obtained from these substrates.[354] The preparation of such heterocyclic boranes was discussed at **15-16.** The overall conversion of a diene or triene to a cyclic alcohol has been described by Brown[355] as "stitching" with boron and "riveting" with carbon.



76 77

Though the mechanism has not been investigated thoroughly, it has been shown to be intramolecular by the failure to find crossover products when mixtures of boranes are used.[355] The following scheme, involving three boron-to-carbon migrations, has been suggested.



78 79 80

The purpose of the ethylene glycol is to intercept the boronic anhydride (80), which otherwise forms polymers that are difficult to oxidize. As we shall see in **18-23** and **18-24,** it is possible to stop the reaction after only one or two migrations have taken place.

Method 1 $R_3B + CHCl_2OMe \xrightarrow[2.\ H_2O_2 - NaOH]{1.\ LiOCEt_3 - THF} R_3COH$

Method 2 $R_3B + CN^- \xrightarrow{THF} \underset{81}{R_3B-CN^-} \xrightarrow[2.\ NaOH - H_2O_2]{1.\ excess\ (CF_3CO)_2O} R_3COH$

There are two other methods for achieving the conversion R3B $\rightarrow$ R_3COH, which often give better results: (1) treatment with α,α-dichloromethyl methyl ether and the base lithium triethylcarboxide[356] (2) treatment with a suspension of sodium cyanide in THF followed by reaction of the resulting trialkylcyanoborate (81) with an excess (>2 mol) of trifluoroacetic anhydride.[357] All the above migrations take place with retention of configuration at the migrating carbon.[358]

Several other methods for the conversion of boranes to tertiary alcohols are also known.[359]

If the reaction between trialkylboranes and carbon monoxide **(18-23)** is carried out in the presence of water followed by addition of NaOH, the product is a secondary alcohol. If H_2O_2 is added along with the NaOH, the corresponding ketone is obtained instead.[360] Various functional groups (e.g., OAc, COOR, CN) may be present in R without being affected,[361] though if they are in the a or (3 position relative to the boron atom, difficulties may be encountered. The use of an equimolar

$$\underset{81}{R_3\bar{B}-CN^-} \xrightarrow[2.\ H_2O_2 - OH^-]{1.\ (CF_3CO)_2O} RCOR$$

amount of trifluoroacetic anhydride leads to the ketone rather than the tertiary alcohol.[362] By this procedure thexylboranes RR'R"B (R" =thexyl) can be converted to unsymmetrical ketones RCOR'.[363] Variations of this methodology have been used to prepare optically active alcohols.[364]

For another conversion of trialkylboranes to ketones, see **18-26**.[365] Other conversions of boranes to secondary alcohols are also known.[366]

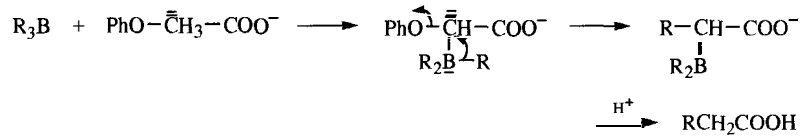
OS **VII,** 427. Also see OS VI, 137.

18-24 *Conversion of Boranes to Primary Alcohols, Aldehydes, or Carboxylic Acids*

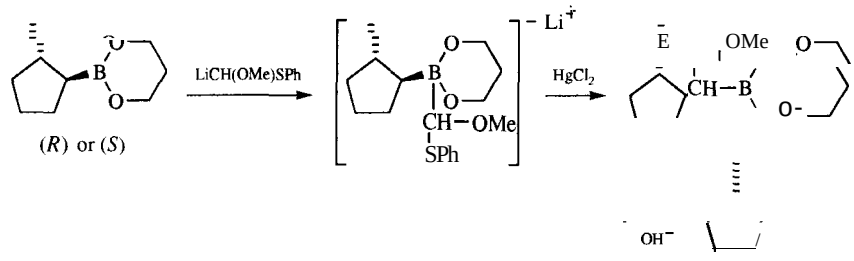
$$R_3B + CO \xrightarrow[2.\ H_2O_2 - OH^-]{1.\ LiBH_4} RCH_2OH$$

$$R_3B + CO \xrightarrow[2.\ H_2O_2 - NaH_2PO_4 - Na_2HPO_4]{1.\ LiAlH(OMe)_3} RCHO$$

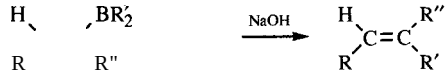
When the reaction between a trialkylborane and carbon monoxide **(18-23)** is carried out in the presence of a reducing agent such as lithium borohydride or potassium triisopropoxyborohydride, the reduction agent intercepts the intermediate 78, so that only one boron-to-carbon migration takes place, and the product is hydrolyzed to a primary alcohol or oxidized to an aldehyde.[367] This procedure wastes two of the three R groups, but this problem can be avoided by the use of B-alkyl-9-BBN derivatives (p. 1013). Since only the 9-alkyl group migrates, this method permits the conversion in high yield of an alkene to a primary alcohol or aldehyde containing one more carbon.[368] When B-alkyl-9-BBN derivatives are treated with CO and lithium tri-*tert*-butoxyaluminum hydride,[369] other functional groups (e.g., CN and ester) can be present in the alkyl group without being reduced.[370] Boranes can be directly converted to carboxylic acids by reaction with the dianion of phenoxyacetic acid.[371]



Boronic esters, $RB(OR')_2$, react with methoxy(phenylthio)methyllithium, LiCH(OMe)SPh, to give salts, which, after treatment with $HgCl_2$, and then H_2O_2, yield aldehydes.[372] This synthesis has been made enantioselective, with high ee values (>99%), by the use of an optically pure boronic ester,[373] for example:

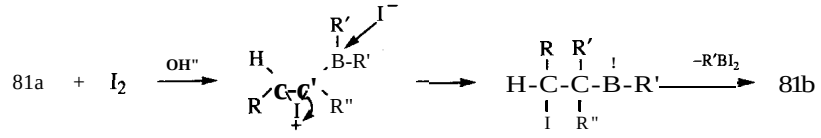


18-25 *Conversion of Vinylic Boranes to Alkenes*



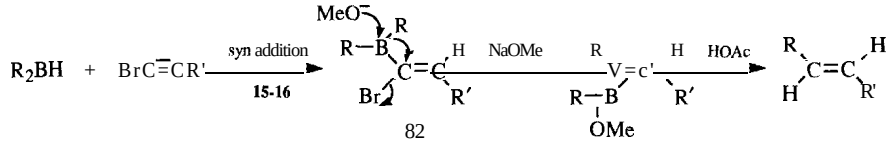
81a **81b**

The reaction between trialkylboranes and iodine to give alkyl iodides was mentioned at **12-28.** When the substrate contains a vinylic group, the reaction takes a different course,[374] with one of the R' groups migrating to the carbon, to give alkenes, **81b.**[375] The reaction is stereospecific in two senses: (1) if the groups R and R" are cis in the starting compound, they will be trans in the product **81a;** (2) there is retention of configuration within the migrating group R'.[376] Since vinylic boranes can be prepared from alkynes **(15-16),** this is a method for the addition of R' and H to a triple bond. If R" = H, the product is a (Z) alkene. The mechanism is believed to be



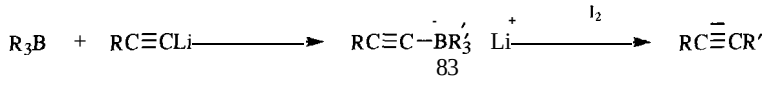
When R' is vinylic, the product is a conjugated diene.[377]

In another procedure, the addition of a dialkylborane to a 1-haloalkyne produces an α-halo vinylic borane (**82**).[378] Treatment of this with NaOMe gives the rearrangement shown, and protonolysis of the product

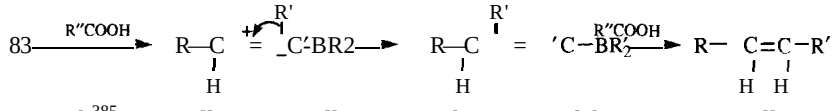


produces the (*E*)-alkene.[376] If R is a vinylic group the product is a 1,3-diene.[379] If one of the groups is thexyl, the other migrates.[380] This extends the scope of the synthesis, since dialkylboranes where one R group is thexyl are easily prepared. A combination of both of the procedures described above results in the preparation of trisubstituted alkenes.[381] The entire conversion of haloalkyne to alkene can be carried out in one reaction vessel, without isolation of intermediates. An aluminum counterpart of the a-halo vinylic borane procedure has been reported.[382]

18-26 *Formation of Alkynes, Alkenes, and Ketones from Boranes and Acetylides*



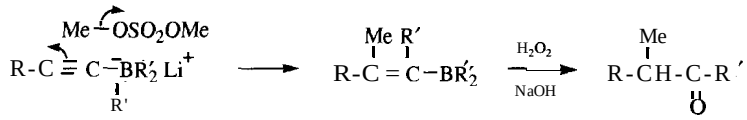
A hydrogen directly attached to a triple-bond carbon can be replaced in high yield by an alkyl or an aryl group, by treatment of the lithium acetylide with a trialkyl- or triarylborane, followed by reaction of the lithium alkynyltrialkylborate 83 with iodine.[383] The R' group may be primary or secondary alkyl as well as aryl, so the reaction has a broader scope than the older reaction 10-110.[384] The R group may be alkyl, aryl, or hydrogen, though in the last-mentioned case satisfactory yields are obtained only if lithium acetylide-ethylenediamine is used as the starting



compound.[385] Optically active alkynes can be prepared by using optically active thexylborinates, RR″BOR′ (R" = thexyl), where R is chiral, and $LiC{\equiv}CSiMe_3$.[386] The reaction can be adapted to the preparation of alkenes[341] by treatment of 83 with an electrophile such as propanoic acid[387] or tributyltin chloride.[388] The reaction with Bu_3SnCl produces the (Z) alkene stereoselectively.

Treatment of 83 with an electrophile such as methyl sulfate, allyl bromide, or triethyloxonium borofluoride, followed by oxidation of the resulting vinylic borane

gives a ketone (illustrated for methyl sulfate):[389]

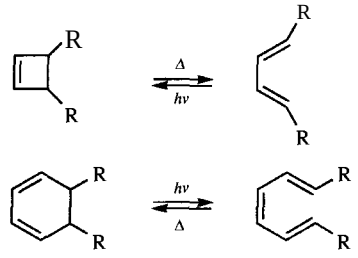


Non-1,2 Rearrangements

A. *Electrocyclic Rearrangements*

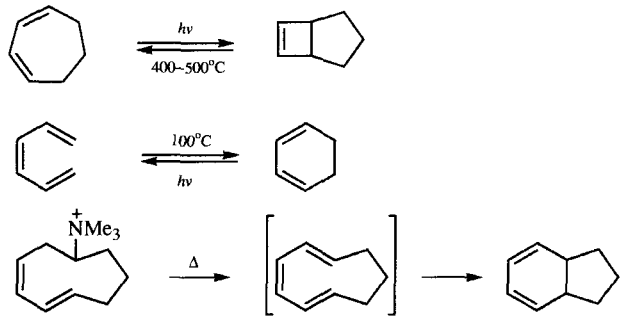
18-27 *Electrocyclic Rearrangements of Cyclobutenes and 1,3-Cyclohexadienes*

(4)*SECO*-1/4/DETACHMENT; (4)*CYCLO*-1/4/ATTACHMENT
(6)*SECO*-1,6/DETACHMENT; *(6)CYCLO*-1/6/ATTACHMENT



Cyclobutenes and 1,3-dienes can be interconverted by treatment with UV light or with heat.[390] The thermal reaction is generally not reversible (though exceptions[391] are known), and many cyclobutenes have been converted to 1,3-dienes by heating at temperatures between 100 and 200°C. The photochemical conversion can in principle be carried out in either direction, but most often 1,3-dienes are converted to cyclobutenes rather than the reverse, because the dienes are stronger absorbers of light at the wavelengths used.[392] In a similar reaction, 1,3-cyclohexadienes interconvert with 1,3,5-trienes, but in this case the ring-closing process is generally favored thermally and the ring-opening process photochemically, though exceptions are known in both directions.[393]

Some examples follow:



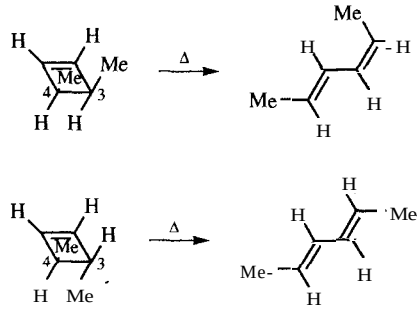
Not isolated

An interesting example of l,3-cyclohexadiene-l,3,5-triene interconversion is the reaction of norcaradienes to give cycloheptatrienes.[395] Norcaradienes give this reaction so readily (because they are *cis*-1,2-divinylcyclopropanes, see p. 1445)

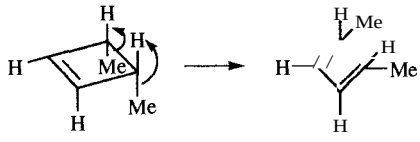
Norcaradiene

that they cannot generally be isolated, though some exceptions are known (see also p. 1087).[396]

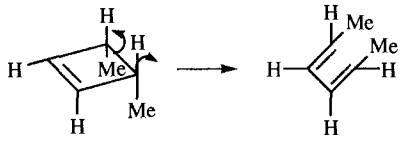
These reactions, called *electrocyclic rearrangements*,[397] take place by pericyclic mechanisms. The evidence comes from stereochemical studies, which show a remarkable stereospecificity whose direction depends on whether the reaction is induced by heat or light. For example, it was found for the thermal reaction that *cis*-3,4-dimethylcyclobutene gave only *cis,trans*-2,4-hexadiene, while the trans isomer gave only the trans-trans diene:[398]



This is evidence for a four-membered cyclic transition state and arises from conrotatory motion about the C-3—C-4 bond. It is called conrotatory because both movements are clockwise (or both counterclockwise). Because both rotate in the same direction, the cis isomer gives the cis-trans diene:[399]



The other possibility *(disrotatory* motion) would have one moving clockwise while the other moves counterclockwise; the cis isomer would have given the cis-cis diene (shown) or the trans-trans diene:



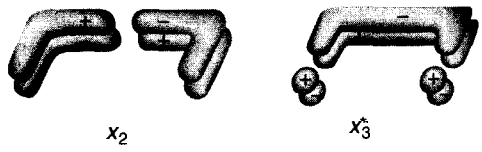


FIGURE 18.1 Symmetries of the χ_2 and χ_{33}^* orbitals of a conjugated diene.

If the motion had been disrotatory, this would still have been evidence for a cyclic mechanism. If the mechanism were a diradical or some other kind of noncyclic process, it is likely that no stereospecificity of either kind would have been observed. The reverse reaction is also conrotatory. In contrast, the photochemical cyclobutene 1,3-diene interconversion is *disrotatory* in either direction.[400] On the other hand, the cyclohexadiene 1,3,5-triene interconversion shows precisely the opposite behavior. The thermal process is *disrotatory*, while the photochemical process is *conrotatory* (in either direction). These startling results are a consequence of the symmetry rules mentioned in Chapter 15 (p. 1068).[401] As in the case of cycloaddition reactions, we will use the frontier-orbital and Möbius–Hückel approaches.[402]

The Frontier-Orbital Method[403]

As applied to these reactions, the frontier-orbital method may be expressed: *A bond will open in such a way that the resulting p orbitals will have the symmetry of the highest occupied n orbital of the product.* In the case of cyclobutenes, the HOMO of the product in the thermal reaction is the χ_2 orbital (Fig. 18.1). Therefore, in a thermal process, the cyclobutene must open so that on one side the positive lobe lies above the plane, and on the other side below it. Thus the substituents are forced into conrotatory motion (Fig. 18.2).

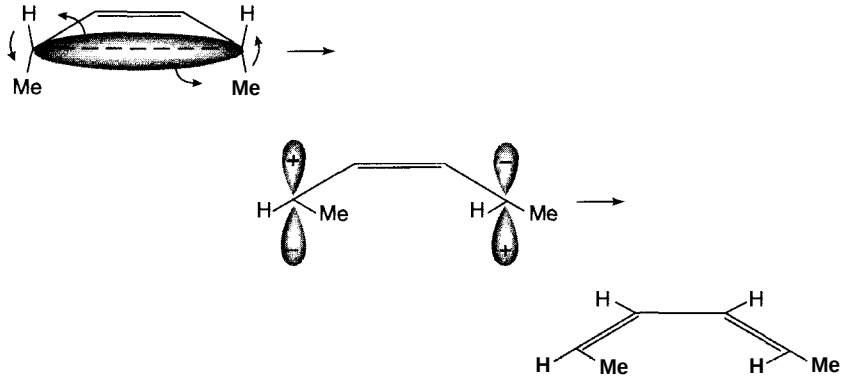

FIGURE 18.2 Thermal ring opening of 1,2-dimethylcyclobutene. The two hydrogens and two methyls are forced into conrotatory motion so that the resulting *p* orbitals have the symmetry of the HOMO of the diene.

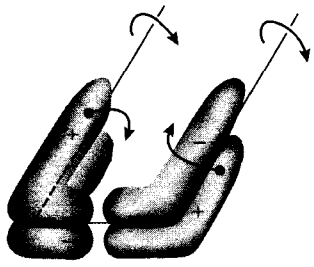

FIGURE 18.3 Thermal ring closing of a 1,3-diene. Conrotatory motion is required for two + lobes to overlap.

On the other hand, in the photochemical process, the HOMO of the product is now the χ_3 orbital (Fig. 18.1), and in order for the *p* orbitals to achieve this symmetry (the two plus lobes on the same side of the plane), the substituents are forced into disrotatory motion.

We may also look at this reaction from the opposite direction (ring closing). For this direction the rule is that *those lobes of orbitals that overlap (in the HOMO) must be of the same sign.* For thermal cyclization of butadienes, this requires conrotatory motion (Fig. 18.3). In the photochemical process the HOMO is the χ_3 orbital, so that disrotatory motion is required for lobes of the same sign to overlap.

The Möbius–Hückel Method[405]

As we saw on p. 1070, in this method we choose a basis set of *p* orbitals and look for sign inversions in the transition state. Figure 18.4 shows a basis set for a 1,3-diene. It is seen that disrotatory ring closing (Fig. 18.4*a*) results in overlap of plus lobes only, while in conrotatory closing (Fig. 18.4*b*) there is one overlap of a plus with a minus lobe. In the first case, we have zero sign inversions, while in the second there is one sign inversion. With zero (or an even number of) sign inversions, the disrotatory transition state is a Hiickel system, and so is allowed thermally only if the total number of electrons is $4n + 2$ (p. 1071). Since the total here is 4, the disrotatory process is not allowed. On the other hand, the conrotatory process, with one sign inversion, is a Mobius system, which is thermally allowed if the total number is An. The conrotatory process is therefore allowed thermally. For the photochemical reactions the rules are reversed: A reaction with An electrons requires a Hiickel system, so only the disrotatory process is allowed.

Both the frontier–orbital and the Möbius-Hiickel methods can also be applied to the cyclohexadiene 1,3,5-triene reaction; in either case the predicted result is that for the thermal process, only the disrotatory pathway is allowed, and for the

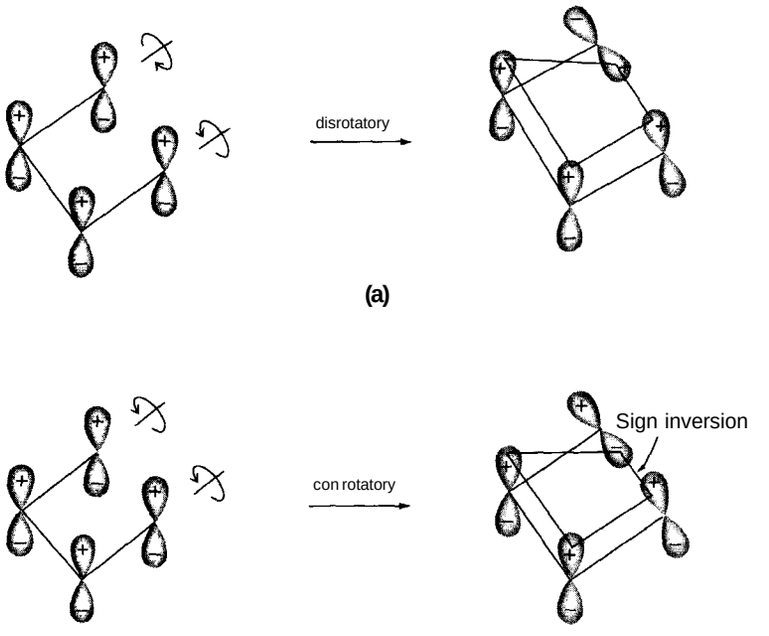

FIGURE 18.4 The 1,3-diene–cyclobutene interconversion. The orbitals shown are *not* MOs, but a basis set of *p* atomic orbitals. (a) Disrotatory ring closure gives zero sign inversions. *(b)* Conrotatory ring closure gives one sign inversion. We could have chosen to show any other basis set (e.g., another basis set would have two plus lobes above the plane and two below). This would change the number of sign inversions, but the disrotatory mode would still have an even number of sign inversions, and the conrottory mode an odd number, whichever basis set was chosen.

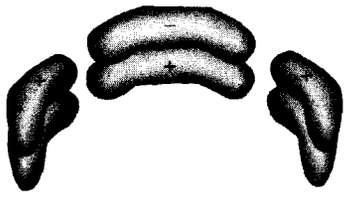
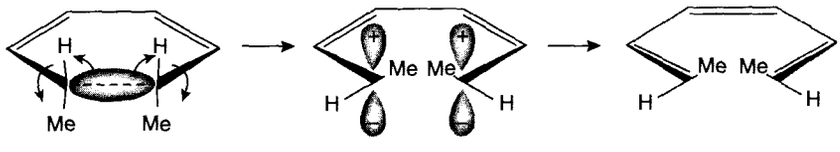
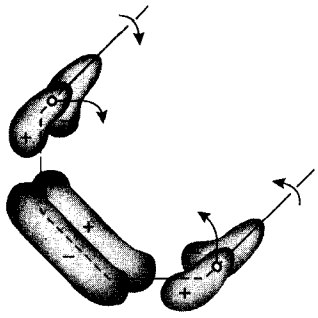
photochemical process, only the conrotatory. For example, for a 1,3,5-triene, the symmetry of the HOMO is



In the thermal cleavage of cyclohexadienes, then, the positive lobes must lie on the same side of the plane, requiring disrotatory motion:



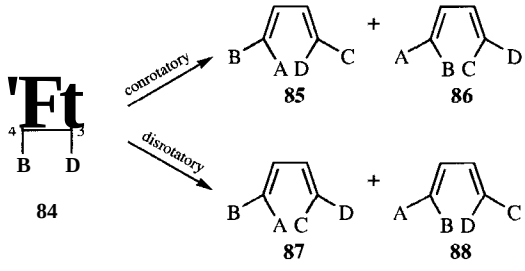
Disrotatory motion is also necessary for the reverse reaction, in order that the orbitals that overlap may be of the same sign:



All these directions are reversed for photochemical processes, because in each case a higher orbital, with inverted symmetry, is occupied.

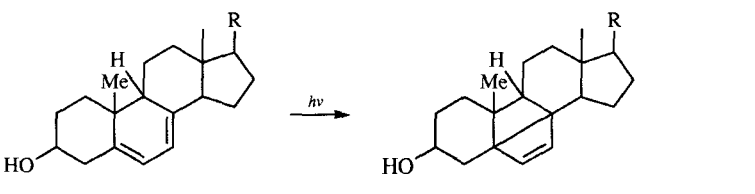
In the Möbius-Hiickel approach, diagrams similar to Figure 18.4 can be drawn for this case. Here too, the disrotatory pathway is a Hiickel system and the conrotatory pathway a Möbius system, but since six electrons are now involved, the thermal reaction follows the Hiickel pathway and the photochemical reaction the Möbius pathway.

In the most general case, there are four possible products that can arise from a given cyclobutene or cyclohexadiene: two from the conrotatory and two from the disrotatory pathway. For example, conrotatory ring opening of 84 gives either 85 or 86, while disrotatory opening gives either 87 or 88. The orbital-symmetry rules tell us when a given reaction will operate by the conrotatory and when by the disrotatory mode, but they do not say which of the two possible conrotatory or disrotatory pathways will be followed. It is often possible, however, to make such predictions on

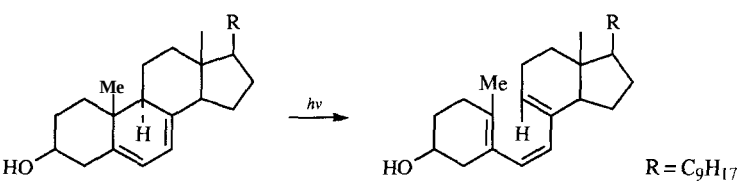


steric grounds. For example, in the opening of 84 by the disrotatory pathway, 87 arises when groups A and C swing in toward each other (clockwise motion around C-4, counterclockwise around C-3), while 88 is formed when groups B and D swing in and A and C swing out (clockwise motion around C-3, counterclockwise around C-4). We therefore predict that when A and C are larger than B and D, the predominant or exclusive product will be 88, rather than 87. Predictions of this kind have largely been borne out.[404] There is evidence, however, that steric effects[405] are not the only factor, and that electronic effects also play a role, which may be even

greater.[406] An electron-donating group stabilizes the transition state when it rotates *outward,* because it mixes with the LUMO; if it rotates *inward,* it mixes with the HOMO, destabilizing the transition state.[407] The compound 3-formylcyclobutene provided a test. Steric factors would cause the CHO (an electron-withdrawing group) to rotate outward; electronic effects would cause it to rotate inward. The experiment showed inward rotation.[408]



89

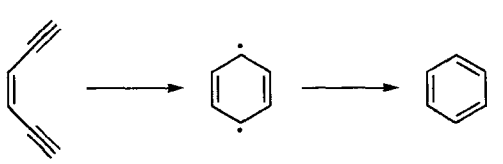


90 **91**

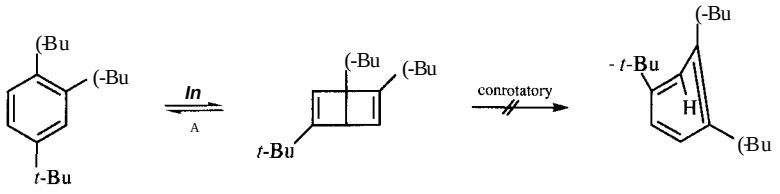
$R = C_9H_{17}$

Cyclohexadienes are of course 1,3-dienes, and in certain cases it is possible to convert them to cyclobutenes instead of to 1,3,5-trienes.[409] An interesting example is found in the pyrocalciferols. Photolysis of the syn isomer 89 (or of the other syn isomer, not shown) leads to the corresponding cyclobutene,[410] while photolysis of the anti isomers (one of them is 90) gives the ring-opened 1,3,5-triene (91). This difference in behavior is at first sight remarkable, but is easily explained by the orbital-symmetry rules. Photochemical ring opening to a 1,3,5-triene must be conrotatory. If 89 were to react by this pathway, the product would be the triene 91, but this compound would have to contain a *trans*-cyclohexene ring (either the methyl group or the hydrogen would have to be directed inside the ring). On the other hand, photochemical conversion to a cyclobutene must be disrotatory, but if 90 were to give this reaction, the product would have to have a trans-fused ring junction. Compounds with such ring junctions are known (p. 162) but are very strained. Stable trans-cyclohexenes are unknown (p. 186). Thus, 89 and 90 give the products they do owing to a combination of orbital-symmetry rules and steric influences.

A variation of this process is the *Bergnan cyclization*,[411] where an ene-diyne cyclizes to a biradical and then aromatizes, for example:

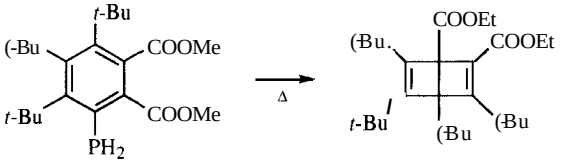


Simply heating the en-diyne will usually lead to aromatization via this pathway.[412]



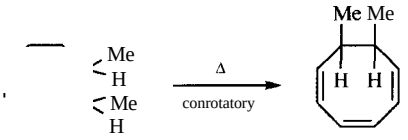
92 93 94

The 1,3-diene cyclobutene interconversion can even be applied to benzene rings. For example,[413] photolysis of 1,2,4-tri-*tert*-butylbenzene (92) gives 1,2,5-tri-*tert*-butyl[2.2.0]hexadiene (93, a Dewar benzene).[414] The reaction owes its success to the fact that once 93 is formed, it cannot, under the conditions used, revert to 92 by either a thermal or a photochemical route. The orbital-symmetry rules prohibit thermal conversion of 93 to 92 by a pericyclic mechanism, because thermal conversion of a cyclobutene to a 1,3-diene must be conrotatory, and conrotatory reaction of 93 would result in a 1,3,5-cyclohexatriene containing one trans double bond (94), which is of course too strained to exist. Compound 93 cannot revert to 92 by a photochemical pathway either, because light of the frequency used to excite 92 would not be absorbed by 93. This is thus another example of a molecule that owes its stability to the orbital-symmetry rules (see p. 1083). Pyrolysis of 93 does give 92, probably by a diradical mechanism.[415] In the case of 95 and 96, the Dewar benzene is actually more stable than the benzene. Compound 95 rearranges to 96 in 90% yield at 120°.[416] In this case, thermolysis of the benzene gives the Dewar benzene (rather than the reverse), because of the strain of four adjacent *tert*-butyl groups on the ring.



95 96

A number of electrocyclic reactions have been carried out with systems of other sizes, for example, conversion of the 1,3,5,7-octatetraene (97) to the cyclooctatriene (**98**).[417] The stereochemistry of these reactions can be predicted in a similar manner.



97 98

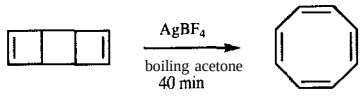
The results of such predictions can be summarized according to whether the number of electrons involved in the cyclic process is of the form *An* or *An + 2* (where *n* is any

integer including zero).

	Thermal Reaction	Photochemical Reaction
$4n$	Conrotatory	Disrotatory
$4n + 2$	Disrotatory	Conrotatory

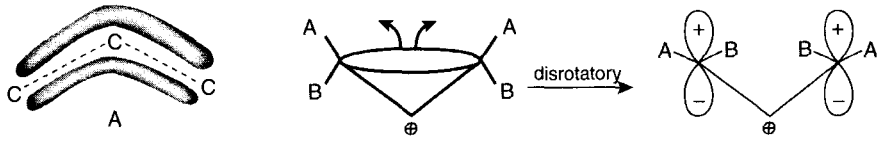
Although the orbital-symmetry rules predict the stereochemical results in almost all cases, it is necessary to recall (p. 1070) that they only say what is allowed and what is forbidden, but the fact that a reaction is allowed does not necessarily mean that the reaction takes place, and if an allowed reaction does take place, it does not *necessarily* follow that a concerted pathway is involved, since other pathways of lower energy may be available.[418] Furthermore, a "forbidden" reaction might still be made to go, if a method of achieving its high activation energy can be found. This was, in fact, done for the cyclobutene butadiene interconversion (cis-3,4-dichloro-cyclobutene gave the forbidden *cis,cis*- and *trans,trans*-1,4-dichloro-1,3-butadienes, as well as the allowed cis, trans isomer) by the use of IR laser light.[419] This is a thermal reaction. The laser light excites the molecule to a higher vibrational level (p. 307), but not to a higher electronic state.

As is the case for [2 + 2] cycloaddition reactions (15-61), certain forbidden electrocyclic reactions can be made to take place by the use of metallic catalysts.[420] An example is the silver ion-catalyzed conversion of tricyclo[4.2.0.0^{2,5}]octa-3,7-diene to cyclooctatetraene:[421]

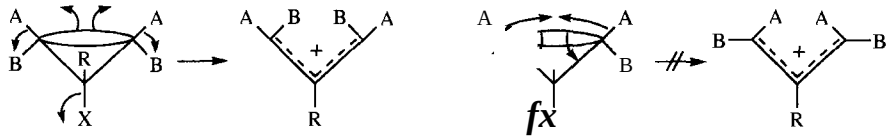


This conversion is very slow thermally (i.e., without the catalyst) because the reaction must take place by a disrotatory pathway, which is disallowed thermally.[422]

The ring opening of cyclopropyl cations (pp. 437, 1399) is an electrocyclic reaction and is governed by the orbital symmetry rules.[423] For this case we invoke the rule that the s bond opens in such a way that the resulting *p* orbitals have the symmetry of the highest occupied orbital of the product, in this case, an allylic cation. We may recall that an allylic system has three molecular orbitals (p. 38). For the cation, with only two electrons, the highest occupied orbital is the one of the lowest energy (A). Thus, the cyclopropyl cation must undergo a disrotatory ring

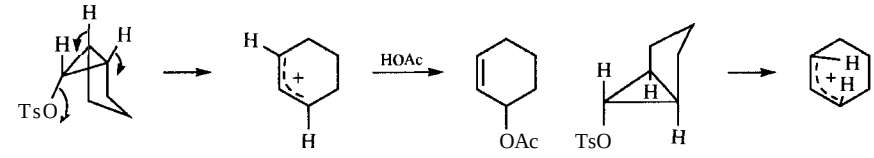


opening in order to maintain the symmetry. (Note that, in contrast, ring opening of the cyclopropyl *anion* must be conrotatory,[424] since in this case it is the next orbital of the allylic system which is the highest occupied, and this has the opposite symmetry.[425]) However, it is very difficult to generate a free cyclopropyl cation (p. 438), and it is likely that in most cases, cleavage of the s bond is concerted with departure of the leaving group in the original cyclopropyl substrate. Of course, this means that the *s* bond provides anchimeric assistance to the removal of the leaving group (an S_N2 type process), and we would expect that such assistance should come from the backside. This has an important effect on the direction of ring opening. The orbital-symmetry rules require that the ring opening be disrotatory, but as we have seen, there are two disrotatory pathways and the rules do not tell us which is preferred. But the fact that the *s* orbital provides assistance from the backside means that the two substituents that are trans to the leaving group must move *outward*, not inward.[426] Thus, the disrotatory pathway that is followed is the one shown in C, not the one shown in D, because the former puts the electrons of the σ bond on the side opposite that of the leaving group.[427] Strong confirmation of this picture[428] comes



C D

from acetolysis of *endo*- (99) and *exo*-bicyclo[3,1,0]hexyl-6-tosylate **(100).** The groups trans to the tosylate must move outward. For **99** this means that the two hydrogens can go outside the framework of the six-membered ring, but for **100** they are forced to go inside. Consequently, it is not surprising that the rate ratio for



99 100

solvolysis of **99:100** was found to be >2.5 x 10^6 and that at 150°C, **100** did not solvolyze at all.[429] This evidence is kinetic. Unlike the cases of the cyclobutene 1,3-diene and cyclohexadiene 1,3,5-triene interconversions, the direct product here is a cation, which is not stable but reacts with a nucleophile and loses some of its steric integrity in the process, so that much of the evidence has been of the kinetic type rather than from studies of product stereochemistry. However, it has been shown by investigations in superacids, where it is possible to keep the cations intact and to study their structures by NMR, that in all cases studied the cation that is predicted by these rules is in fact formed.[430]

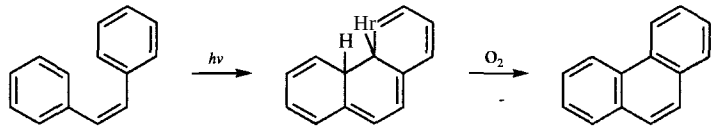
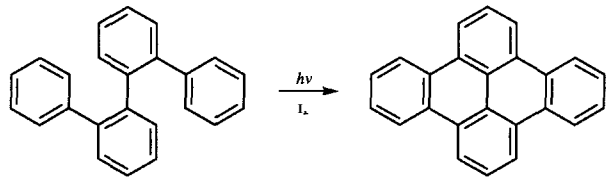
18-28 *Conversion of Stilbenes to Phenanthrenes*

(6)*CYCLO*-DE-HYDROGEN-COUPLING (OVERALL TRANSFORMATION)



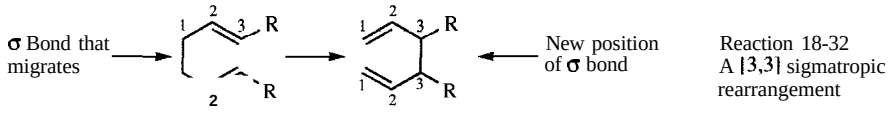
Stilbenes can be converted to phenanthrenes by irradiation with UV light[431] in the presence of an oxidizing agent such as dissolved molecular oxygen, $FeCl_3$, Pd—C,[432] or iodine.[433] The reaction is a photochemically allowed conrotatory[434] conversion of a 1,3,5-hexatriene to a cyclohexadiene, followed by removal of two hydrogen atoms by the oxidizing agent. The intermediate dihydrophenanthrene has been isolated.[435] The use of substrates containing heteroatoms (e.g., PhN=NPh) allows the formation of heterocyclic ring systems. The actual reacting species must be the *cis*-stilbene, but *trans*-stilbenes can often be used, because they are isomerized to the cis isomers under the reaction conditions. The reaction can be extended to the preparation of many fused aromatic systems, for example,[436]



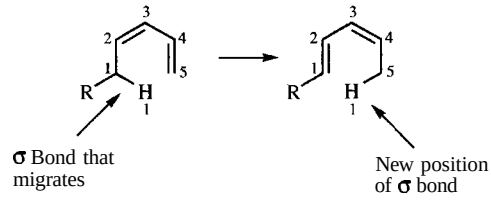
though not all such systems give reaction.[437]

B. *Sigmatropic Rearrangements*

A sigmatropic rearrangement is defined[438] as migration, in an uncatalyzed intramolecular process, of a σ bond, adjacent to one or more *n* systems, to a new position in a molecule, with the *n* systems becoming reorganized in the process. Examples are



Reaction 18-32
A [3,3] sigmatropic rearrangement

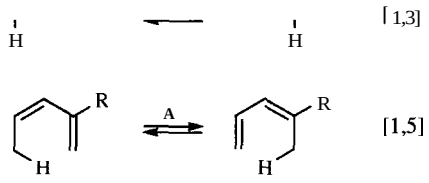


Reaction 18-39
A [1,5] sigmatropic rearrangement

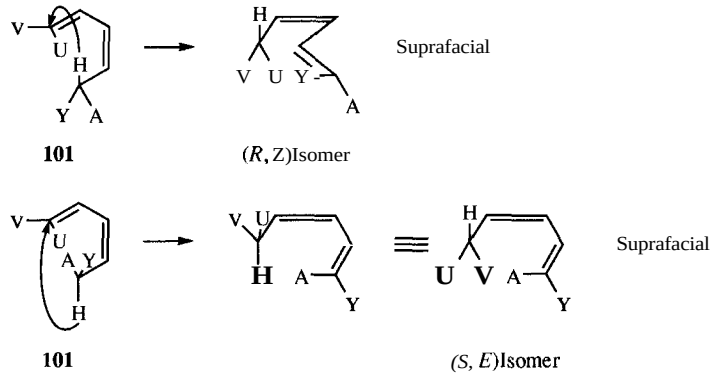
The *order* of a sigmatropic rearrangement is expressed by two numbers set in brackets: *[i,j]*. These numbers can be determined by counting the atoms over which each end of the s bond has moved. Each of the original termini is given the number 1. Thus in the first example above, each terminus of the s bond has migrated from C-1 to C-3, so the order is [3,3]. In the second example, the carbon terminus has moved from C-1 to C-5, but the hydrogen terminus has not moved at all, so the order is [1,5].

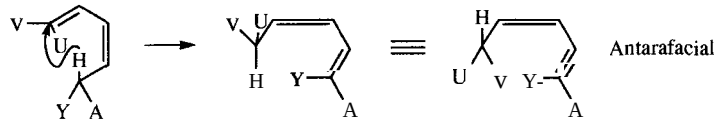
18-29 *[1,j] Sigmatropic Migrations of Hydrogen*

1/ → 3/HYDROGEN-MIGRATION; 1/ → 5/HYDROGEN-MIGRATION

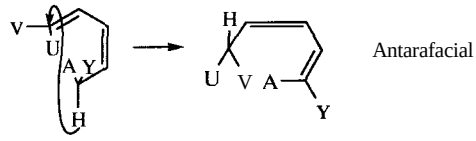


Many examples of thermal or photochemical rearrangements in which a hydrogen atom migrates from one end of a system of *n* bonds to the other have been reported,[439] though the reaction is subject to geometrical conditions. Pericyclic mechanisms are involved, and the hydrogen must, in the transition state, be in contact with both ends of the chain at the same time. This means that for [1,5] and longer rearrangements, the molecule must be able to adopt the cisoid conformation. Furthermore, there are two geometrical pathways by which any sigmatropic rearrangement can take place, which we illustrate for the case of a [1,5] sigmatropic rearrangement,[440] starting with a substrate of the form 101, where the migration origin is an asymmetric carbon atom and U ≠ V. In one of the two pathways, the hydrogen moves along the top or bottom face of the *n* system. This is called *suprafacial migration.* In the other pathway, the hydrogen moves *across* the *n* system, from top to bottom, or vice versa. This is *antarafacial* migration. Altogether, a single isomer like 101 can give four products. In a suprafacial migration, H can move across the top of the *n* system (as drawn above) to give the *(R, Z)* isomer, or it can





101 (*S*, Z)Isomer



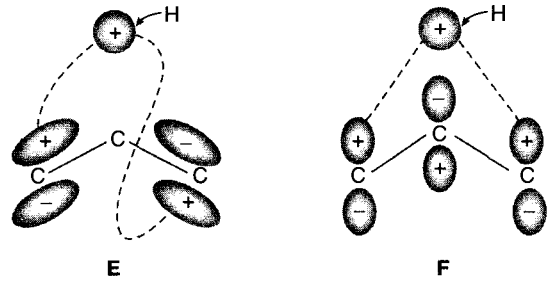
101 (*R*, *E*)Isomer

rotate 180° and move across the bottom of the *n* system to give the *(S, E)* isomer.[441] The antarafacial migration can similarly lead to two diastereomers, in this case the *(S,* Z) and *(R, E)* isomers.

In any given sigmatropic rearrangement, only one of the two pathways is allowed by the orbital-symmetry rules; the other is forbidden. To analyze this situation we first use a modified frontier–orbital approach.[442] We will imagine that in the transition state the migrating H atom breaks away from the rest of the system, which we may treat as if it were a free radical.

Imaginary transition state for a [1,3] sigmatropic rearrangement

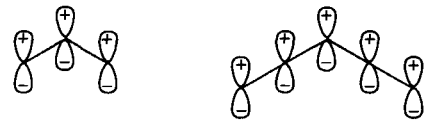
Note that this is not what actually takes place; we merely imagine it in order to be able to analyze the process. In a [1,3] sigmatropic rearrangement the imaginary transition state consists of a hydrogen atom and an allyl radical. The latter species (p. 38) has three *n* orbitals, but the only one that concerns us here is the HOMO which, in a thermal rearrangement is E. The electron of the hydrogen atom is of course in a 1*s* orbital, which has only one lobe. The rule governing sigmatropic migration of hydrogen is *the H must move from a plus to a plus or from a minus to a minus*



E **F**

lobe, of the HOMO; it cannot move to a lobe of opposite sign.[443] Obviously, the only way this can happen in a thermal [1,3] sigmatropic rearrangement is if the migration is antarafacial. Consequently, the rule predicts that antarafacial thermal [1,3] sigmatropic rearrangements are allowed, but the suprafacial pathway is forbidden. However, in a photochemical reaction, promotion of an electron means that F is now the HOMO; the suprafacial pathway is now allowed and the antarafacial pathway forbidden.

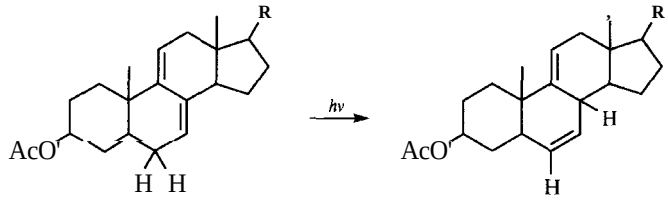
A similar analysis of [1,5] sigmatropic rearrangements shows that in this case the thermal reaction must be suprafacial and the photochemical process antarafacial. For the general case, with odd-numbered *j*, we can say that *[l,j]* suprafacial migrations are allowed thermally when *j* is of the form 4n + 1, and photochemically when *j* has the form *An*— 1; the opposite is true for antarafacial migrations.



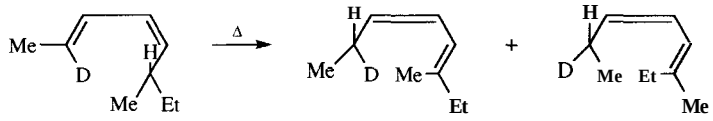
G H

As expected, the Möbius–Hückel method leads to the same predictions. Here we look at the basis set of orbitals shown in G and H for [1,3] and [1,5] rearrangements, respectively. A [1,3] shift involves four electrons, so an allowed thermal pericyclic reaction must be a Möbius system (p. 1070) with one or an odd number of sign inversions. As can be seen in G, only an antarafacial migration can achieve this. A [1,5] shift, with six electrons, is allowed thermally only when it is a Hiickel system with zero or an even number of sign inversions; hence it requires a suprafacial migration.

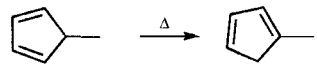
The actual reported results bear out this analysis. Thus a thermal [1,3] migration is allowed to take place only antarafacially, but such a transition state would be extremely strained, and thermal [1,3] sigmatropic migrations of hydrogen are unknown.[444] On the other hand, the photochemical pathway allows suprafacial [1,3] shifts, and a few such reactions are known, an example being[445]



The situation is reversed for [1,5] hydrogen shifts. In this case, the thermal rearrangements, being suprafacial, are quite common, while photochemical rearrangements are rare.[446] Two examples of the thermal reaction are



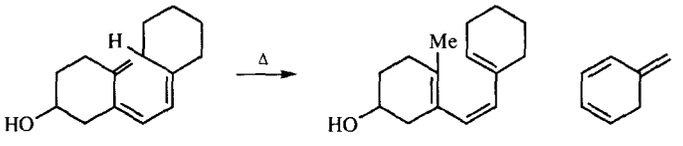
Ref. 447



Ref. 448

Note that the first example bears out the stereochemical prediction made earlier. Only the two isomers shown were formed. In the second example, migration can > continue around the ring. Migrations of this kind are called *circumambulatory rearrangements.*[449] Such migrations are known for cyclopentadiene, pyrrole, and phosphole derivatives.[450] [1,5] Hydrogen shifts are also known with vinyl aziridines.[451]

The rare [1,4] hydrogen transfer has been observed in radical cyclizations.[452] With respect to [1,7] hydrogen shifts, the rules predict the thermal reaction to be antarafacial. Unlike the case of [1,3] shifts, the transition state is not too greatly strained, and such rearrangements have been reported, for example,[453]

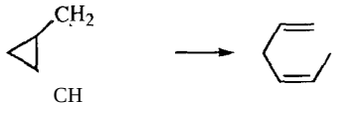


102

Photochemical [1,7] shifts are suprafacial and, not surprisingly, many of these have been observed.[454]

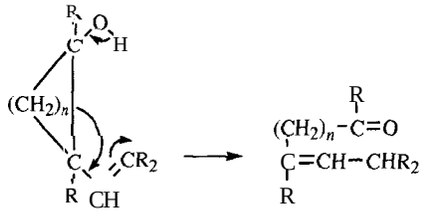
The orbital symmetry rules also help us to explain, as on pages 1083 and 1433, the unexpected stability of certain compounds. Thus, **102** could, by a thermal [1,3] sigmatropic rearrangement, easily convert to toluene, which of course is far more stable because it has an aromatic sextet. Yet **102** has been prepared and is stable at dry ice temperature and in dilute solutions.[455]

Analogs of sigmatropic rearrangements in which a cyclopropane ring replaces one of the double bonds are also known, for example,[456]

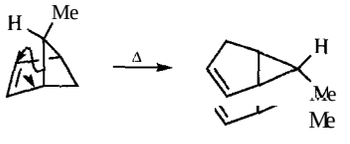


A homodienyl [1,5] shift

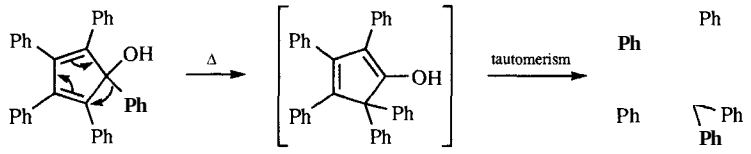
The reverse reaction has also been reported.[457] 2-Vinylcycloalkanols[458] undergo an analogous reaction, as do cyclopropyl ketones (see p. 1450 for this reaction).



18-30 *[1,j] Sigmatropic Migrations of Carbon*



[1,3] Migration of alkyl[459]



[1,5] Migration of phenyl[460]

Sigmatropic migrations of alkyl or aryl groups[461] are less common than the corresponding hydrogen migrations.[462] When they do take place, there is an important difference. Unlike a hydrogen atom, whose electron is in a 1*s* orbital with only one lobe, a carbon free radical has its odd electron in a *p* orbital that has *two lobes of opposite sign.* Therefore, if we draw the imaginary transition states for this case (see p. 1438), we see that in a thermal suprafacial [1,5] process (Fig. 18.5), symmetry can be conserved only if the migrating carbon moves in such a way that the lobe which was originally attached to the *n* system remains attached to the *n* system. This can happen only if configuration is *retained within the migrating group.* On the other hand, thermal suprafacial [1,3] migration (Fig. 18.6) *can* take place if the migrating carbon switches lobes. If the migrating carbon was originally bonded by its minus

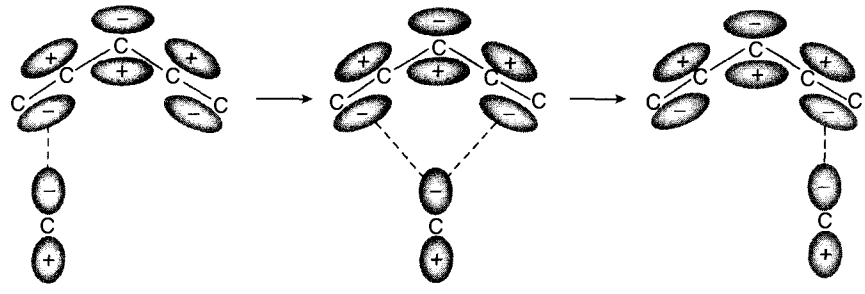


FIGURE 18.5 Hypothetical orbital movement for a thermal [1,5] sigmatropic migration of carbon. To move from one — lobe to the other — lobe, the migrating carbon use only its own — lobe, retaining its configuration.

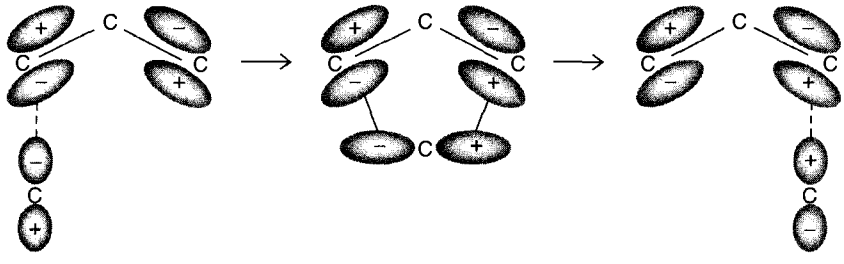

FIGURE 18.6 Hypothetical orbital movement for a thermal [1,3] sigmatropic migration of carbon. The migrating carbon moves from a — to a + lobe, requiring it to switch its own bonding lobe from — to +, inverting its configuration.

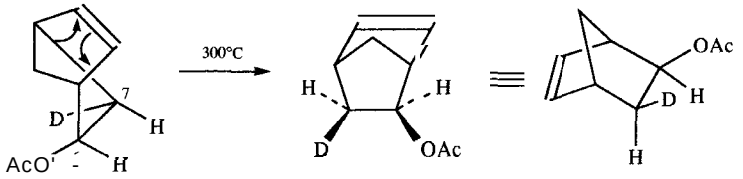
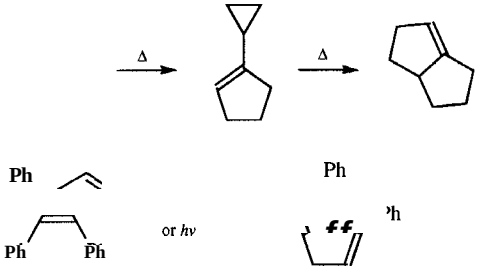
lobe, it must now use its plus lobe to form the new C–C bond. Thus, configuration in the migrating group will be *inverted.* From these considerations we predict that suprafacial [1, *j*] sigmatropic rearrangements in which carbon is the migrating group are always allowed, both thermally and photochemically, but that thermal [1,3] migrations will proceed with inversion and thermal [1,5] migrations with retention of configuration within the migrating group. More generally, we can say that suprafacial [1, *j*] migrations of carbon in systems where $j = An - 1$ proceed with inversion thermally and retention photochemically, while systems where $j = An + 1$ show the opposite behavior. Where antarafacial migrations take place, all these predictions are of course reversed.



103 **104**

The first laboratory test of these predictions was the pyrolysis of deuterated *endo*-bicyclo[3.2.0]hept-2-en-6-yl acetate **(103),** which gave the *exo*-deuterio-*exo*-norbornyl acetate (104).[463] Thus, as predicted by the orbital-symmetry rules, this thermal suprafacial [1,3] sigmatropic reaction took place with complete inversion at C-7. Similar results have been obtained in a number of other cases.[464] However, similar studies of the pyrolysis of the parent hydrocarbon of **103,** labeled with D at C-6 and C-7, showed that while most of the product was formed with inversion at C-7, a significant fraction (11–29%) was formed with retention.[465] Other cases of lack of complete inversion are also known.[466] A diradical mechanism has been invoked to explain such cases.[467] There is strong evidence for a radical mechanism for some [1,3] sigmatropic rearrangements.[468] Photochemical suprafacial [1,3] migrations of carbon have been shown to proceed with retention, as predicted.[469]

Although allylic vinylic ethers generally undergo [3,3] sigmatropic rearrangements **(18-33),** they can be made to give the [1,3] kind, to give aldehydes, for



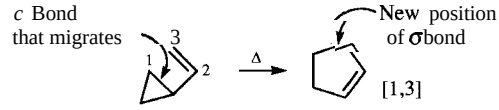
example, by treatment with $LiClO_4$ in diethyl ether.[470] In this case the C–O bond undergoes a 1,3 migration from the O to the end vinylic carbon. When the vinylic ether is of the type $ROCR'=CH_2$, ketones RCH_2COR' are formed. There is evidence

that this [1,3] sigmatropic rearrangement is not concerted, but involves dissociation of the substrate into ions.[470]

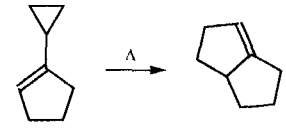
Thermal suprafacial [1,5] migrations of carbon have been found to take place with retention,[471] but also with inversion.[472,473] A diradical mechanism has been suggested for the latter case.[472]

Simple nucleophilic, electrophilic, and free-radical 1,2 shifts can also be regarded as sigmatropic rearrangements (in this case, [1,2] rearrangements). We have already (p. 1377) applied similar principles to such rearrangements to show that nucleophilic 1,2 shifts are allowed, but the other two types are forbidden unless the migrating group has some means of delocalizing the extra electron or electron pair.

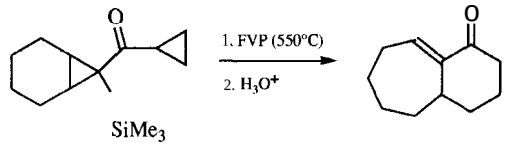
18-31 *Conversion of Vinylcyclopropanes to Cyclopentenes*



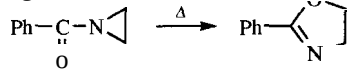
The thermal expansion of a vinylcyclopropane to a cyclopentene ring[474] is a special case of a [1,3] sigmatropic migration of carbon, though it can also be considered an internal [$_{\pi}2 + {}_{\sigma}2$] cycloaddition reaction (see 15-61). It is known as a *vinylcyclopropane rearrangement.* The reaction has been carried out on many vinylcyclopropanes bearing various substituents in the ring or on the vinyl group and has been extended to 1,1-dicyclopropylethene[475] and (both thermally[476] and photochemi-



cally[477]) to vinylcyclopropenes. This rearrangement can be catalyzed by rhodium and silver compounds, and has been used to form rings.[478] Another variation converts α-trimethylsilylcyclopropyl ketones to ring-expanded conjugated ketones via flash vacuum pyrolysis at 550°C, for example.[479]

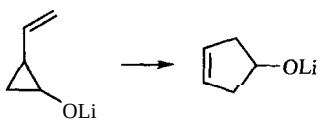


Various heterocyclic analogs[480] are also known, for example,[481]



Two competing reactions are the homodienyl [1,5] shift (if a suitable H is available, see **18-29),** and simple cleavage of the cyclopropane ring, leading in this case to a diene (see 18-3).

Vinylcyclobutanes can be similarly converted to cyclohexenes,[482] but larger ring compounds do not generally give the reaction.[483] Though high temperatures (as high as 500° C) are normally required for the thermal reaction, the lithium salts of *2*-vinylcyclopropanols rearrange at 25°C.[484]



Salts of 2-vinylcyclobutanols behave analogously.[485]

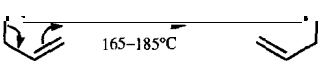
The reaction rate has also been greatly increased by the addition of a one-electron oxidant tris-(4-bromophenyl)aminium hexafluoroantimonate $Ar_3N^{\cdot+}$ SbF_6^- (Ar = *p*-bromophenyl).[486] This reagent converts the substrate to a cation radical, which undergoes ring expansion much faster.[487]

The mechanisms of these ring expansions are not certain. Both concerted[488] and diradical[489] pathways have been proposed,[490] and it is possible that both pathways operate, in different systems.

For the conversion of a vinylcyclopropane to a cyclopentene in a different way, see OS 68, 220.

18-32 *The Cope Rearrangement*

(3/4/) → (1/6/)-*SIGMA*-MIGRATION



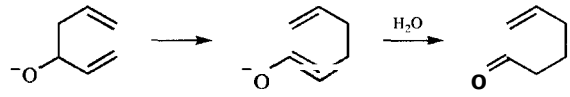
Z = Ph, RCO, etc.

When 1,5-dienes are heated, they isomerize, in a [3,3] sigmatropic rearrangement known as the *Cope rearrangement* (not to be confused with the Cope elimination reaction, 17-8).[491] When the diene is symmetrical about the 3,4 bond, we have the unusual situation where a reaction gives a product identical with the starting material:[492]

Therefore, a Cope rearrangement can be detected only when the diene is not symmetrical about this bond. Any 1,5-diene gives the rearrangement; for example, 3-methyl-l,5-hexadiene heated to 300°C gives 1,5-heptadiene.[493] However, the reaction takes place more easily (lower temperature required) when there is a group

on the 3 or 4 carbon with which the new double bond can conjugate. The reaction is obviously reversible and produces an equilibrium mixture of the two 1,5-dienes, which is richer in the thermodynamically more stable isomer. However, the reaction is not generally reversible[494] for 3-hydroxy-1,5-dienes, because the product tautomerizes to the ketone or aldehyde:

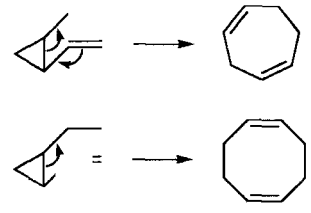
This reaction, called the *oxy-Cope rearrangement*,[495] has proved highly useful in synthesis.[496] The oxy-Cope rearrangement is greatly accelerated (by factors of 10^{10}–10^{17}) if the alkoxide is used rather than the alcohol.[497] In this case the direct product is the enolate ion, which is hydrolyzed to the ketone.



aza-Cope rearrangements are also known.[498]

The 1,5-diene system may be inside a ring or part of an allenic system (this example illustrates both of these situations):[499]

but the reaction does not take place when one of the double bonds is part of an aromatic system (e.g., 4-phenyl-1-butene).[500] When the two double bonds are in vinylic groups attached to adjacent ring positions, the product is a ring four carbons larger. This has been applied to divinylcyclopropanes and cyclobutanes:[501]

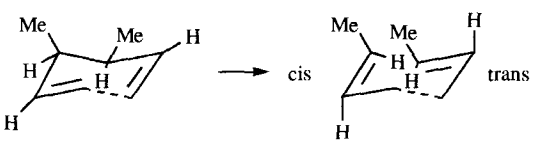


Indeed, *cis*-1,2-divinylcyclopropanes give this rearrangement so rapidly that they generally cannot be isolated at room temperature,[502] though exceptions are known.[503] When heated, 1,5-diynes are converted to 3,4-dimethylenecyclobutenes.[504] A rate-determining Cope rearrangement is followed by a very rapid electrocyclic (18-27) reaction. The interconversion of 1,3,5-trienes and cyclohexadienes

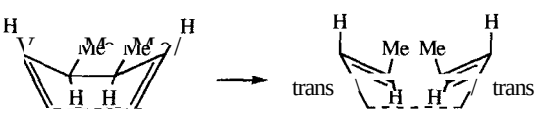
(in **18-27)** is very similar to the Cope rearrangement, though in **18-27,** the 3,4 bond goes from a double bond to a single bond rather than from a single bond to no bond.

Like [2 + 2] cycloadditions (p. 1082), Cope rearrangements of simple 1,5-dienes can be catalyzed by certain transition metal compounds. For example, the addition of $PdCl_2(PhCN)_2$ causes the reaction to take place at room temperature.[505] This can be quite useful synthetically, because of the high temperatures required in the uncatalyzed process.

As we have indicated with our arrows, the mechanism of the uncatalyzed Cope rearrangement is a simple six-centered pericyclic process.[506] Since the mechanism is so simple, it has been possible to study some rather subtle points, among them the question of whether the six-membered transition state is in the boat or the chair form.[507] For the case of 3,4-dimethyl-l,5-hexadiene it was demonstrated conclusively that the transition state is in the chair form. This was shown by the stereospecific nature of the reaction: The meso isomer gave the cis-trans product, while the (±) compound gave the trans-trans diene.[508] If the transition state is in the chair form (e.g., taking the meso isomer), one methyl must be "axial" and the other "equatorial" and the product must be the cis-trans alkene:



There are two possible boat forms for the transition state of the meso isomer. One leads to a trans-trans product;

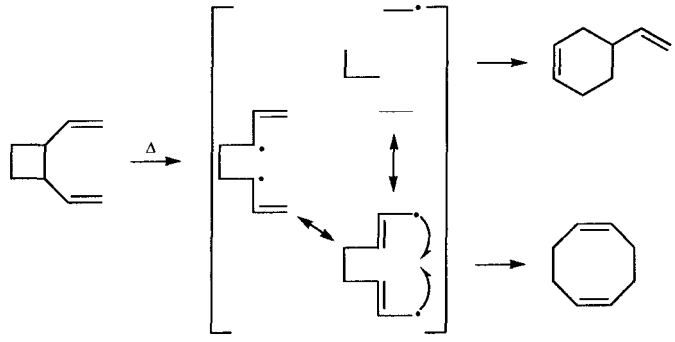


the other to a cis-cis alkene. For the (±) pair the predictions are just the opposite: There is just one boat form, and it leads to the cis-trans alkene, while one chair form ("diaxial" methyls) leads to the cis-cis product and the other ("diequatorial" methyls) predicts the trans-trans product. Thus the nature of the products obtained demonstrates that the transition state is a chair and not a boat.[509] However, 3,4-dimethyl-1,5-hexadiene is free to assume either the chair or boat (it prefers the chair), but other compounds are not so free. Thus 1,2-divinylcyclopropane (p. 1445) can react *only* in the boat form, demonstrating that such reactions are not impossible.[510]

Because of the nature of the transition state[511] in the pericyclic mechanism, optically active substrates with a chiral carbon at C-3 or C-4 transfer the chirality to the product, making this an enantioselective synthesis (see p. 1451 for an example in the mechanistically similar Claisen rearrangement).[512]

Not all Cope rearrangements proceed by the cyclic six-centered mechanism. Thus *cis*-1,2-divinylcyclobutane (p. 1445) rearranges smoothly to 1,5-cycloocta-

diene, since the geometry is favorable. The trans isomer also gives this product, but



the main product is 4-vinylcyclohexene (resulting from **18-31).** This reaction can be rationalized as proceeding by a diradical mechanism,[513] though it is possible that at least part of the cyclooctadiene produced comes from a prior epimerization of the *trans*- to the *cis*-divinylcyclobutane followed by Cope rearrangement of the latter.[514]

It has been suggested that another type of diradical two-step mechanism may be preferred by some substrates.[515] Indeed, a nonconcerted Cope rearrangement has been reported.[516] In this pathway,[517] the 1,6 bond is formed before the 3,4 bond breaks:

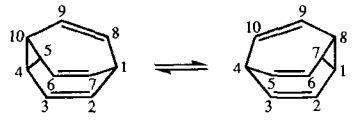
This is related to the *Bergman cyclization* that was introduced in **18-27.**

It was pointed out earlier that a Cope rearrangement of 1,5-hexadiene gives 1,5-hexadiene. This is a *degenerate Cope rearrangement* (p. 1380). Another molecule that undergoes it is bicyclo[5.1.0]octadiene (105).[518] At room temperature the NMR

105 **105**

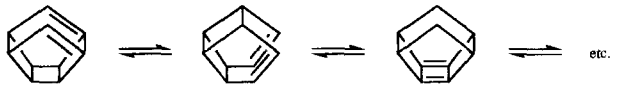
spectrum of this compound is in accord with the structure shown on the left. At 180°C it is converted by a Cope reaction to a compound equivalent to itself. The interesting thing is that at 180°C the NMR spectrum shows that what exists is an equilibrium mixture of the two structures. That is, at this temperature the molecule rapidly (faster than 10^3 times per second) changes back and forth between the two structures. This is called *valence tautomerism* and is quite distinct from resonance, even though only electrons shift.[519] The positions of the nuclei are not the same in the two structures. Molecules like **105** that exhibit valence tautomerism (in this case, at 180°C) are said to have *fluxional* structures. It may be recalled that *cis*-1,2-divinylcyclopropane does not exist at room temperature because it rapidly rearranges to 1,4-cycloheptadiene (p. 1445), but in **105** the *cis*-divinylcyclopropane structure is frozen into the molecule in both structures. Several other compounds

with this structural feature are also known. Of these, *bullvalene* **(106)** is especially interesting.



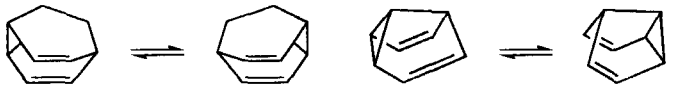
106

The Cope rearrangement shown changes the position of the cyclopropane ring from 4,5,10 to 1,7,8. But the molecule could also have undergone rearrangements to put this ring at 1,2,8 or 1,2,7. Any of these could then undergo several Cope rearrangements. In all, there are 10!/3, or > 1.2 million tautomeric forms, and the cyclopropane ring can be at any three carbons that are adjacent. Since each of these tautomers is equivalent to all the others, this has been called an infinitely degenerate Cope rearrangement. Bullvalene has been synthesized and its 'H NMR spectrum determined.[520] At -25°C there are two peaks with an area ratio of 6:4. This is in accord with a single non-tautomeric structure. The six are the vinylic protons and the four are the allylic ones. But at 100°C the compound shows only one NMR peak, indicating that we have here a truly unusual situation where the compound rapidly interchanges its structure among 1.2 million equivalent forms.[521] The ^{13}C NMR spectrum of bullvalene also shows only one peak at 100°C.[522]



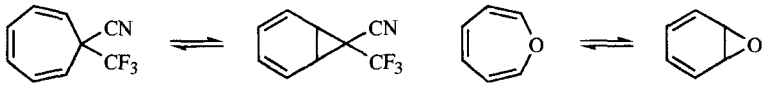
107

Another compound for which degenerate Cope rearrangements result in equivalence for all the carbons is *hypostrophene* (107).[523] In the case of the compound *barbaralane* (108) (bullvalene in which one CH=CH has been replaced by a CH_2):



108 **109**

there are only two equivalent tautomers.[524] However, NMR spectra indicate that even at room temperature a rapid interchange of both tautomers is present, though by about — 100°C this has slowed to the point where the spectrum is in accord with a single structure. In the case of *semibullvalene* (109) (barbaralane in which the CH_2 has been removed), not only is there a rapid interchange at room temperature, but even at — 110°C.[525] **109** has the lowest energy barrier of any known compound capable of undergoing the Cope rearrangement.[526]

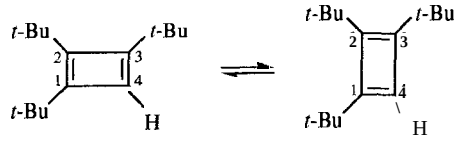


110 **111** **Oxepin** **Benzene oxide**

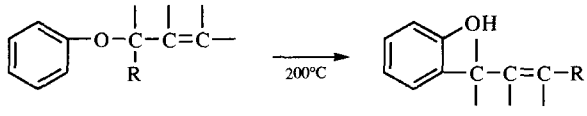
The molecules taking part in a valence tautomerization need not be equivalent. Thus, NMR spectra indicate that a true valence tautomerization exists at room temperature between the cycloheptatriene 110 and the norcaradiene (111).[527] In this case one isomer (111) has the *cis*-1,2-divinylcyclopropane structure, while the other does not. In an analogous interconversion, benzene oxide[528] and oxepin exist in a tautomeric equilibrium at room temperature.[529]

Bullvalene and hypostrophene are members of a group of compounds all of whose formulas can be expressed by the symbol $(CH)_{10}$.[530] Many other members of this group are known. Similar groups of $(CH)_n$ compounds exist for other even-numbered values of 'V.[530] For example, there are 20 possible $(CH)_8$[531] compounds,[532] and five possible $(CH)_6$ compounds,[533] all of which are known: benzene, prismane (p. 182), Dewar benzene (p. 1433), bicyclopropenyl,[534] and benzvalene.[535]

An interesting example of a valence tautomerism is the case of 1,2,3-tri-*tert*-butylcyclobutadiene (p. 59). There are two isomers, both rectangular, and ^{13}C NMR spectra show that they exist in a dynamic equilibrium, even at - 185°C.[536]

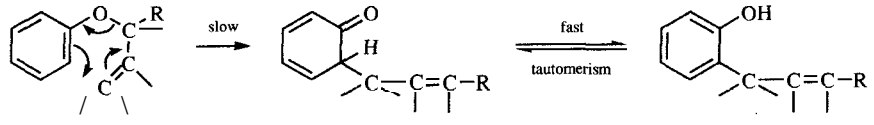


18-33 *The Claisen Rearrangement*

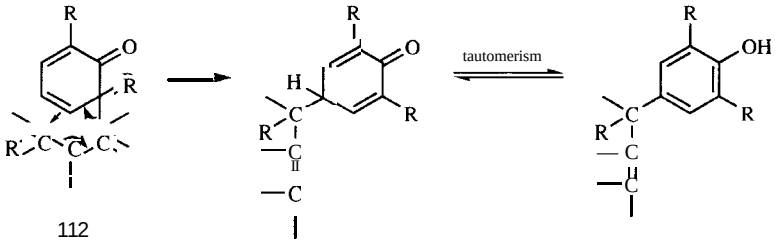


Allylic aryl ethers, when heated, rearrange to *o*-allylphenols in a reaction called the *Claisen rearrangement*.[537] If both ortho positions are filled, the allylic group migrates to the para position (this is often called the *para-Claisen rearrangement*). There is no reaction when the para and both ortho positions are filled. Migration to the meta position has not been observed. In the ortho migration the allylic group always undergoes an allylic shift. That is, as shown above, a substituent a to the oxygen is now γ to the ring (and vice versa). On the other hand, in the para migration there is never an allylic shift: the allylic group is found exactly as it was in the original ether. Compounds with propargylic groups (i.e., groups with a triple bond in the appropriate position) do not generally give the corresponding products.

The mechanism is a concerted pericyclic [3,3] sigmatropic rearrangement[538] and accounts for all these facts. For the ortho rearrangement:



Evidence is the lack of a catalyst, the fact that the reaction is first order in the ether, the absence of crossover products when mixtures are heated, and the presence of the allylic shift, which is required by this mechanism. A retro-Claisen rearrangement is known and its mechanism has been examined.[539] The allylic shift for the ortho rearrangement (and the absence of one for the para) has been demonstrated by ^{14}C labeling, even when no substituents are present. Studies of the transition state geometry have shown that, like the Cope rearrangement, the Claisen rearrangement usually prefers a chair-like transition state.[540] When the ortho positions have no hydrogen, a second [3,3] sigmatropic migration (a Cope reaction) follows:

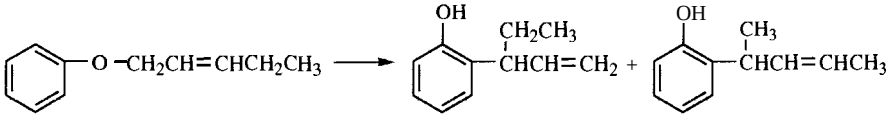


112

and the migrating group is restored to its original structure. Intermediates of structure 112 have been trapped by means of a Diels–Alder reaction.[541]

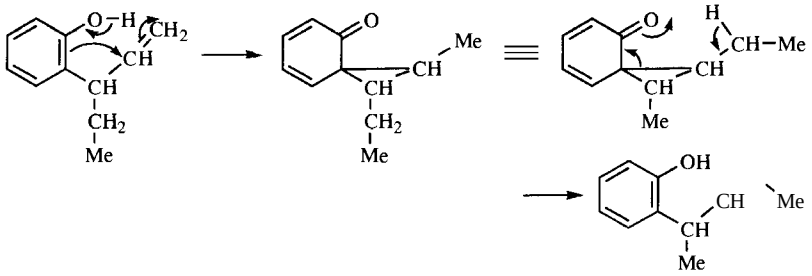
Asymmetric Claisen rearrangement reactions are well known.[542] Chiral Lewis acids have been designed for this purpose.[543] In general, asymmetric [3,3] sigmatropic rearrangements are well known.[544]

Ethers with an alkyl group in the *y* position (ArO—C—C=C—R systems) sometimes give abnormal products, with the (3 carbon becoming attached to the ring:[545]



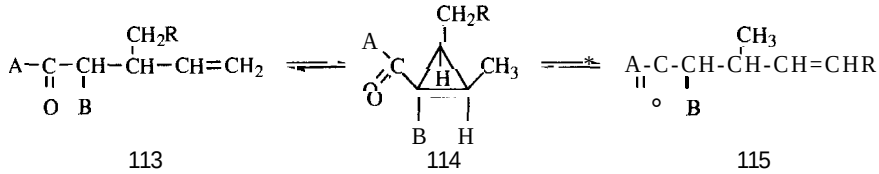
Normal product Abnormal product

It has been established that these abnormal products do not arise directly from the starting ether but are formed by a further rearrangement of the normal product:[546]



This rearrangement, which has been called an *enolene rearrangement,* a *homodienyl* [1,5] *sigmatropic hydrogen shift* (see 18-29), and a [1,5] *homo sigmatropic*

rearrangement, involves a shift of three electron pairs over *seven* atoms. It has been found that this "abnormal" Claisen rearrangement is general and can interconvert the enol forms of systems of the types **113** and **115** through the cyclopropane intermediate **114**.[547]



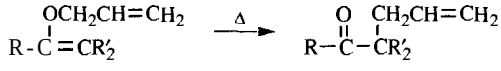
113 114 115

A = H, R, Ar, OR, etc.

B = H, R, Ar, COR, COAr, COOR, etc.

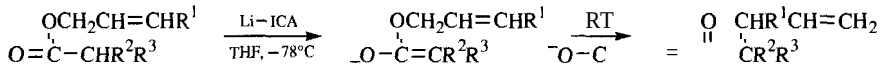
Since the Claisen rearrangement mechanism does not involve ions, it should not be greatly dependent on the presence or absence of substituent groups on the ring.[548] This is the case. Electron-donating groups increase the rate and electron-withdrawing groups decrease it, but the effect is small, with the *p*-amino compound reacting only ~ 10-20 times faster than the *p*-nitro compound.[549] However, solvent effects[550] are greater: rates varied over a 300-fold range when the reaction was run in 17 different solvents.[551] An especially good solvent is trifluoroacetic acid, in which the reaction can be carried out at room temperature.[552] Most Claisen rearrangements are performed without a catalyst, but $AlCl_3$ or BF3 are sometimes used.[553] In this case it may become a Friedel-Crafts reaction, with the mechanism no longer cyclic,[554] and ortho, meta, and para products may be obtained.

Allylic ethers of enols (allylic vinylic ethers) also undergo the Claisen rearrangement;[555] in fact, it was discovered with these compounds first:[556]



In these cases, of course, the final tautomerization does not take place even when R' = H, since there is no aromaticity to restore, and ketones are more stable than enols.[557] The use of water as solvent accelerates the reaction.[558] The mechanism is similar to that with allylic aryl ethers.[559]

It is possible to treat ketones with allyl alcohol and an acid catalyst to give γ,δ-unsaturated ketones directly, presumably by initial formation of the vinylic ethers, and then Claisen rearrangement.[560] In an analogous procedure, the enolates (126) of allylic esters [formed by treatment of the esters with lithium isopropylcyclohexylamide (ICA)] rearrange to γ,δ-unsaturated acids.[561]

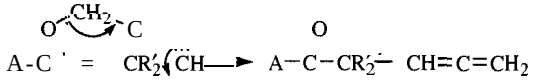


116

Alternatively, the silylketene acetal $R^3R^2C{=}C(OSiR_3)OCH_2CH{=}CHR^1$ is often used instead of 116.[562] This rearrangement also proceeds at room temperature. By

either procedure, the reaction is called the *Ireland–Claisenrearrangement*.[563] Note the presence of the negative charge in **116.** As with the oxy-Cope rearrangement (in **18-34),** negative charges generally accelerate the Claisen reaction,[564] though the extent of the acceleration can depend on the identity of the positive counterion.[565] The Ireland-Claisen rearrangement has been made enantioselective by converting **116** to an enol borinate in which the boron is attached to a chiral group.[566] The Ireland-Claisen rearrangement can be done with amide derivatives also.[567]

A number of expected analogs of the Claisen rearrangement are known, for example, rearrangement of $ArNHCH_2CH{=}CH_2$,[568] of N-allylic enamines, $R_2C{=}CRNRCR_2CR{=}CR_2$,[569] of allylic imino esters, $RC(OCH_2CH{=}CH_2){=}NR$[570] (these have often been rearranged with transition metal catalysts[571]), and of $RCH{=}NRCHRCH_2CH{=}CH_2$. These rearrangements of nitrogen-containing compounds are often called *aza-Cope rearrangements*[572] as described in **18-34.** However, a palladium catalyzed aza-Claisen has been reported.[573] A so-called amine-Claisen rearrangement was reported for N-allyl indoles, when heated in the presence of $BF_3{\cdot}OEt_2$.[574] An *azo-Cope* rearrangement: $CH_2{=}CHCR^1_2CR^2_2N{=}NAr \rightarrow R^1_2C{=}CHCH_2NArN{=}CR^2_2$ has been reported.[575] Propargylic vinylic compounds give allenic aldehydes, ketones, esters, or amides:[576]

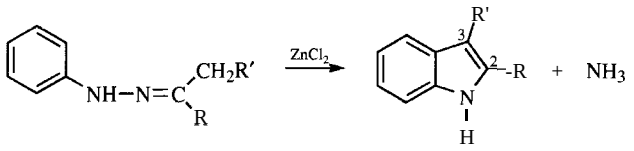


A = H, R, OR, NR_2

The conversion of allylic aryl thioethers $ArSCH_2CH{=}CH_2$ to *o*-allylic thiophenols (the *thio-Claisen rearrangement)* is not feasible, because the latter are not stable[577] but react to give bicyclic compounds.[578] However, many allylic vinylic sulfides do give the rearrangement.[579] Allylic vinylic sulfones (e.g., $H_2C{=}CRCH_2{-}SO_2{-}CH{=}CH_2$), rearrange, when heated in the presence of ethanol and pyridine, to unsaturated sulfonate salts ($CH_2{=}CRCH_2CH_2CH_2SO_3^-$), produced by reaction of the reagents with the unstable sulfene intermediates $CH_2{=}CRCH_2CH_2CH{=}SO_2$.[580] Allylic vinylic sulfoxides rapidly rearrange at room temperature or below.[581]

OS **III,** 418; V, 25; **VI,** 298, 491, 507, 584, 606; **VII,** 177; **VIII,** 251, 536.

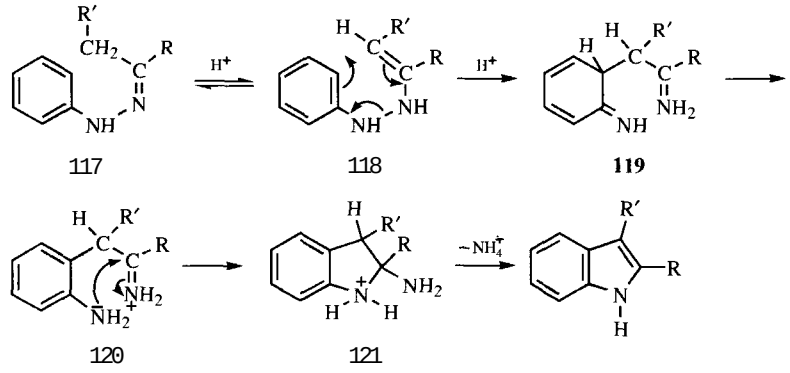
18-34 *The Fischer Indole Synthesis*



When arylhydrazones of aldehydes or ketones are treated with a catalyst, elimination of ammonia takes place and an indole is formed, in the *Fischer indole synthesis.*[582] Zinc chloride is the catalyst most frequently employed, but dozens of others, including other metal halides, proton and Lewis acids, and certain transition metals have also been used. Microwave irradiation has been used to facilitate this reaction.[583] Aniline derivatives react with α-diazoketones, in the presence of a

rhodium catalyst, to give indoles as well.[584] Arylhydrazones are easily prepared by the treatment of aldehydes or ketones with phenylhydrazine **(16-2)** or by aliphatic diazonium coupling (12-7). However, it is not necessary to isolate the arylhydrazone. The aldehyde or ketone can be treated with a mixture of phenylhydrazine and the catalyst; this is now common practice. In order to obtain an indole, the aldehyde or ketone must be of the form $RCOCH_2R'$ (R = alkyl, aryl, or hydrogen).

At first glance the reaction does not seem to be a rearrangement. However, the key step of the mechanism[585] is a [3,3] sigmatropic rearrangement:[586]



117 **118** **119**

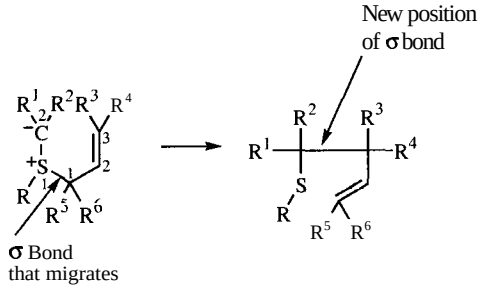
120 **121**

There is much evidence for this mechanism, for example, (1) the isolation of **121**,[587] (2) the detection of **120** by ^{13}C and ^{15}NNMR,[588] (3) the isolation of side products that could only have come from 119,[589] and (4) ^{15}N labeling experiments that showed that it was the nitrogen farther from the ring that is eliminated as ammonia.[590] The main function of the catalyst seems to be to speed the conversion of **117-118.** The reaction can be performed without a catalyst.

OS **III,** 725; IV, 884. Also see OS IV, 657.

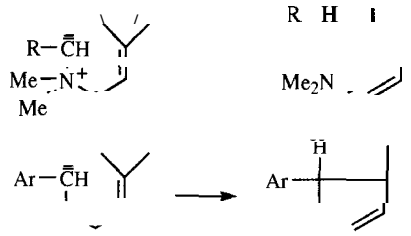
18-35 *[2,3] Sigmatropic Rearrangements*

(2/S-3/) -v (1/5/)-*SIGMA*-MIGRATION



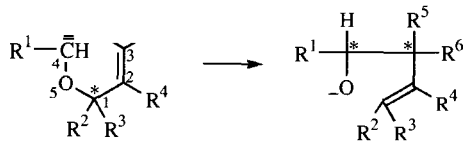
Sulfur ylids bearing an allylic group are converted on heating to unsaturated sulfides.[591] This is a concerted [2,3] sigmatropic rearrangement[592] and has also been demonstrated for the analogous cases of nitrogen ylids[593] and the conjugate bases of

allylic ethers (in the last case it is called the *[2,3] Wittig rearrangement).*[594] It has been argued that the [2,3] Wittig rearrangement demands severe deformation of the molecule in order to proceed.[595] The SmI_2 compound has been shown to induce a [2,3] Wittig rearrangement.[596] The reaction has been extended to certain other systems,[597] even to an all-carbon system.[598]



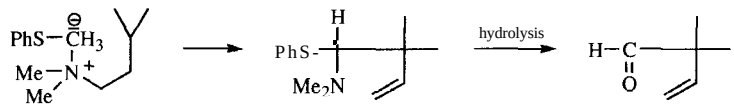
Since the reactions involve migration of an allylic group from a sulfur, nitrogen, or oxygen atom to an adjacent negatively charged carbon atom, they are special cases of the Stevens or Wittig rearrangements (**18-21**, **18-22**). However, in this case the migrating group *must* be allylic (in 18-21 and 18-22 other groups can also migrate). Thus, when the migrating group is allylic, there are two possible pathways: (1) the radical-ion or ion-pair mechanisms (18-21, 18-22) and (2) the concerted pericyclic [2,3] sigmatropic rearrangement. These can easily be told apart, since the latter always involves an allylic shift (as in the Claisen rearrangement), while the former pathway does not.

Of these reactions, the [2,3] Wittig rearrangement in particular has often been used as a means of transferring chirality. The product of this reaction has potential chiral centers at C-3 and C-4 (if $R^5 \neq R^6$), and if the starting

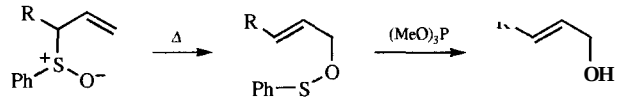


ether is optically active because of a chiral center at C-1, the product may be optically active as well. Many examples are known in which an optically active ether was converted to a product that was optically active because of chirality at C-3, C-4, or both.[599] If a suitable chiral center is present in R^1 (or if a functional group in R^1 can be so converted), then stereocontrol over three contiguous chiral centers can be achieved. Stereocontrol of the new double bond *(E* or *Z)* has also been accomplished.

If an OR or SR group is attached to the negative carbon, the reaction becomes a method for the preparation of β,γ-unsaturated aldehydes, because the product is easily hydrolyzed.[600]

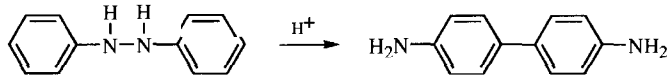


Another [2,3] sigmatropic rearrangement converts allylic sulfoxides to allylically rearranged alcohols by treatment with a thiophilic reagent such as trimethyl phosphite.[601,602] This is often called the *Mislow–Evans rearrangement.* In this case, the migration is from sulfur to oxygen. [2,3] Oxygen-to-sulfur migrations are also known.[603] The Sommelet–Hauser rearrangement **(13-22)** is also a [2,3] sigmatropic arrangement.



OS **VIII,** 427.

18-36 *The Benzidine Rearrangement*



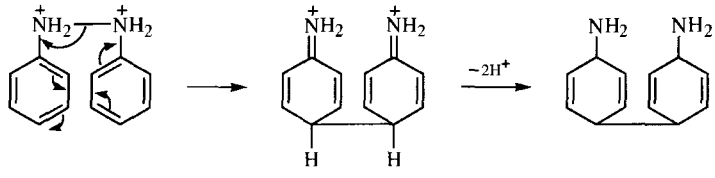
Hydrazobenzene **122**

When hydrazobenzene is treated with acids, it rearranges to give about 70% 4,4'-diaminobiphenyl **(122,** benzidine) and about 30% 2,4'-diaminobiphenyl. This reaction is called the *benzidine rearrangement* and is general for *N,N'*-diarylhydrazines.[604] Usually, the major product is the 4,4'-diaminobiaryl, but four other products may also be produced. These are the 2,4'-diaminobiaryl, already referred to, the 2,2'-diaminobiaryl, and the *o*- and *p*-arylaminoanilines (called *semidines).* The 2,2'- and *p*-arylaminoaniline compounds are formed less often and in smaller amounts than the other two side products. Usually, the 4,4'-diaminobiaryl predominates, except when one or both para positions of the diarylhydrazine are occupied. However, the 4,4'-diamine may still be produced even if the para positions are occupied. If SO_3H, COOH, or Cl (but not R, Ar, or NR_2) is present in the para position, it may be ejected. With dinaphthylhydrazines, the major products are not the 4,4'-diaminobinaphthyls, but the 2,2' isomers. Another side reaction is disproportionation to $ArNH_2$ and ArN=NAr. For example, *p,p'*-$PhC_6H_4NHNHC_6H_4Ph$ gives 88% disproportionation products at 25°C.[605]

The mechanism has been exhaustively studied and several mechanisms have been proposed.[606] At one time it was believed that NHAr broke away from ArNHNHAr and became attached to the para position to give the semidine, which then went on to product. The fact that semidines could be isolated lent this argument support, as did the fact that this would be analogous to the rearrangements considered in Chapter 11 **(11-31-11-35).** However, this theory was killed when it was discovered that semidines could not be converted to benzidines under the reaction conditions. Cleavage into two independent pieces (either ions or radicals) has been ruled out by many types of crossover experiments, which always showed that the two rings of the starting material are in the product; that is, ArNHNHAr' gives no molecules (of any of the five products) containing two Ar groups or two Ar' groups, and mixtures of

ArNHNHAr and Ar'NHNHAr' give no molecules containing both Ar and Ar'. An important discovery was the fact that, although the reaction is always first order in substrate, it can be either first[607] or second[608] order in $[H^+]$. With some substrates the reaction is entirely first order in $[H^+]$, while with others it is entirely second order in $[H^+]$, regardless of the acidity. With still other substrates, the reaction is first order in $[H^+]$ at low acidities and second order at higher acidities. With the latter substrates fractional orders can often be observed,[609] because at intermediate acidities, both processes take place simultaneously. These kinetic results seem to indicate that the actual reacting species can be either the monoprotonated substrate $ArNHNH_2Ar$ or the diprotonated $ArNH_2NH_2Ar$.

Most of the proposed mechanisms[610] attempted to show how all five products could be produced by variations of a single process. An important breakthrough was the discovery that the two main products are formed in entirely different ways, as shown by isotope-effect studies.[611] When the reaction was run with hydrazobenzene labeled with ^{15}N at both nitrogen atoms, the isotope effect was 1.022 for formation of **122,** but 1.063 for formation of 2,4'-diaminobiphenyl. This showed that the N—N bond is broken in the rate-determining step in both cases, but the steps themselves are obviously different. When the reaction was run with hydrazobenzene labeled with ^{14}C at a para position, there was an isotope effect of 1.028 for formation of **122,** but essentially no isotope effect (1.001) for formation of 2,4'-diaminobiphenyl. This can only mean that for **122** formation of the new C—C bond *and* breaking of the N—N bond both take place in the rate-determining step; in other words, the mechanism is concerted. The following [5.5] sigmatropic rearrangement accounts for this:[612]



123

The di-ion (123) was obtained as a stable species in superacid solution at −78°C by treatment of hydrazobenzene with FSO_3H—SO_2 (SO_2ClF).[613] Though the results just given were obtained with hydrazobenzene, which reacts by the diprotonated pathway, monoprotonated substrates have been found to react by the same [5,5] sigmatropic mechanism.[614] Some of the other rearrangements in this section are also sigmatropic. Thus, formation of the *p*-semidine takes place by a [1,5] sigmatropic rearrangement,[615] and the conversion of 2,2'-hydrazonaphthalene to 2,2'-diamino-1,1'-binaphthyl by a [3,3] sigmatropic rearrangement.[616]

2,4'-Diaminobiphenyl is formed by a completely different mechanism, though the details are not known. There is rate-determining breaking of the N—N bond, but the C—C bond is not formed during this step.[617] The formation of the *o*-semidine also takes place by a nonconcerted pathway.[618] Under certain conditions, benzidine rearrangements have been found to go through radical cations.[619]

C. *Other Cyclic Rearrangements*

18-37 *Metathesis of Alkenes*

ALKENE METATHESIS

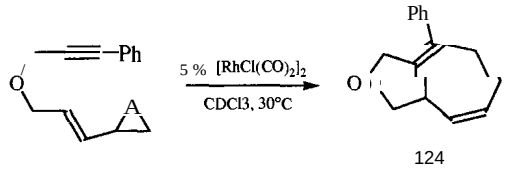
$$CH_3CH{=}CHCH_2CH_3 \xrightarrow[WCl_6-EtOH]{EtAlCl_2} CH_3CH{=}CHCH_3 + CH_3CH_2CH{=}CHCH_2CH_3$$

When alkenes are treated with certain catalysts (most often tungsten, molybdenum,[620] or rhenium complexes), they are converted to other alkenes in a reaction in which the alkylidene groups ($R^1R^2C{=}$) have become interchanged by a process schematically illustrated by the equation:

The reaction is called *metathesis* of alkenes.[621] In the example shown above, 2-pentene (either cis, trans, or a cis-trans mixture) is converted to a mixture of ~ 50% 2-pentene, 25% 2-butene, and 25% 3-hexene. The reaction is an equilibrium and the same mixture can be obtained by starting with equimolar quantities of 2-butene and 3-hexene.[622] In general, the reaction can be applied to a single unsymmetrical alkene, giving a mixture of itself and two other alkenes, or to a mixture of two alkenes, in which case the number of different molecules in the product depends on the symmetry of the reactants. As in the case above, a mixture of $R^1R^2C{=}CR^1R^2$ and $R^3R^4C{=}CR^3R^4$ gives rise to only one new alkene ($R^1R^2C{=}CR^3R^4$), while in the most general case, a mixture of $R^1R^2C{=}CR^3R^4$ and $R^5R^6C{=}CR^7R^8$ gives a mixture of ten alkenes: the original two plus eight new ones. With simple alkenes the proportions of products are generally statistical,[623] which limits the synthetic utility of the reaction since the yield of any one product is low. However, in some cases one alkene may be more or less thermodynamically stable than the rest, so that the proportions are not statistical. Furthermore, it may be possible to shift the equilibrium. For example, 2-methyl-1-butene gives rise to ethylene and 3,4-dimethyl-3-hexene. By allowing the gaseous ethylene to escape, the yield of 3,4-dimethyl-3-hexene can be raised to 95%.[624]

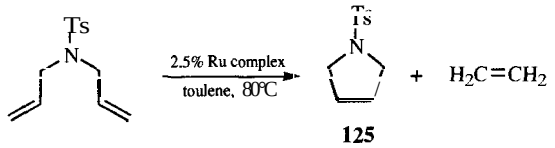
Many catalysts, both homogeneous[625] and heterogeneous,[626] have been used for this reaction. Although there are several examples of the former, the most common today are ruthenium complexes,[627] while among the latter are oxides of Mo, W, and Re deposited on alumina or silica gel.[628] In general, the former group are more useful for synthetic purposes. By choice of the proper catalyst, the reaction has been applied to terminal and internal alkenes, straight chain or branched. The effect of substitution on the ease of reaction is $CH_2{=}{>}RCH_2CH{=}{>}R_2CHCH{=}{>}R_2C{=}$.[629] Dienes can react intermolecularly or intramolecularly.[630] Intermolecular reactions generate rings, usually alkenes or dienes. Alkenes metathesis can be used to form very large rings, including 21-membered lactone rings.[631] Metathesis with vinyl-cyclo-

propyl-alkynes is also known, producing a ring expanded product (see **124**).[632]



124

Catalysts have been developed that are compatible with both water and methanol.[633] The reaction is compatible with the presence of other functional groups such as other alkene units,[634] carbonyl units,[635] and amides (see 125).[636]

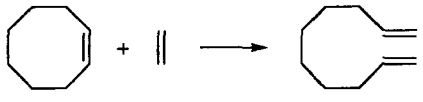


125

Ether groups, including vinyl ethers,[637] allylic ethers,[638] and thioethers[639] are also compatible.

Two cyclic alkenes react to give dimeric dienes,[640] for example,

However, the products can then react with additional monomers and with each other, so that polymers are generally produced, and the cyclic dienes are obtained only in low yield. The reaction between a cyclic and a linear alkene can give an ring-opened diene:[641]



Alkenes containing functional groups[642] do not give the reaction with most of the common catalysts, but some success has been reported with WCl_6– $SnMe_4$[643] and with certain other catalysts.

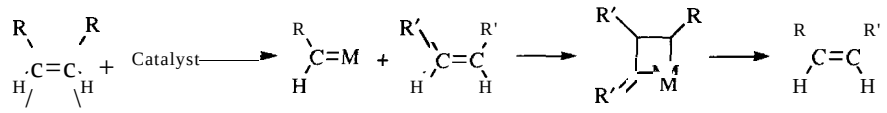
The reaction has also been applied to internal triple bonds:[644]

$$2\,RC{\equiv}CR' \rightleftharpoons RC{\equiv}CR + R'C{\equiv}CR'$$

but it has not been successful for terminal triple bonds.[645] Intramolecular reactions of a double bond with a triple bond are known[646] and a tetracyclic tetraene has been prepared from a poly-yne-diene.[647]

The generally accepted mechanism is a chain mechanism, involving the intervention of a metal–carbene complex (126)[648] and a four-membered ring containing

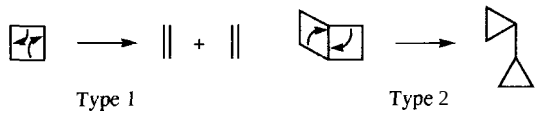
a metal[649] (127).[650]



18-38 *Metal–Ion-Catalyzed σ-Bond Rearrangements*

128 Cubane Cuneane

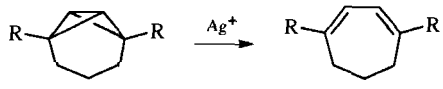
Many highly strained cage molecules undergo rearrangement when treated with metallic ions such as Ag^+, Rh(I), or Pd(II).[651] The bond rearrangements observed can be formally classified into two main types: (1) [2 + 2] ring



Type 1 Type 2

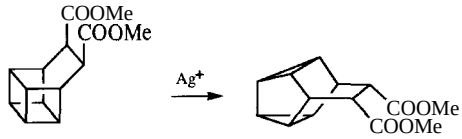
openings of cyclobutanes and (2) conversion of a bicyclo [2.2.0] system to a bicyclopropyl system. The molecule cubane supplies an example of each type (see above). Treatment with Rh(I) complexes converts cubane to tricyclo[4.2.0.$0^{2,5}$]octa-3,7-diene **(128),**[652] an example of type 1, while Ag^+ or Pd(II) causes the second type of reaction, producing cuneane.[653] Other examples

Type 1



129 **130** Ref. 654

Type 2[655]

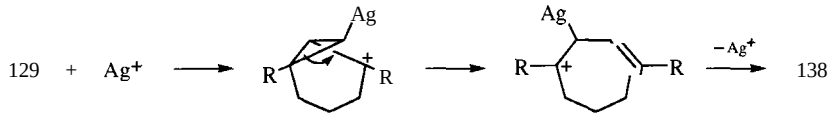


131 Ref. 656

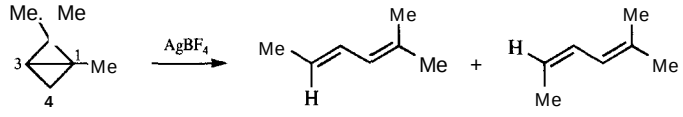
are Compound **131** is the 9,10-dicarbomethyoxy derivative of *snoutane*, pentacyclo[3.3.2.$0^{2,4}$.$0^{3,7}$.$0^{6,8}$]decane.

The mechanisms of these reactions are not completely understood, although relief of strain undoubtedly supplies the driving force. The reactions are thermally forbidden by the orbital-symmetry rules, and the role of the catalyst is to provide low-energy pathways so that the reactions can take place. The type 1 reactions are the reverse of the catalyzed [2 + 2] ring closures discussed at **15-61.** The following

mechanism, in which Ag^+ attacks one of the edge bonds, has been suggested for the conversion of 129 to 130.[657]



Simpler bicyclobutanes can also be converted to dienes, but in this case the products usually result from cleavage of the central bond and one of the edge bonds.[658] For example, treatment of 132 with $AgBF_4$,[659]

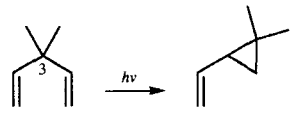


132

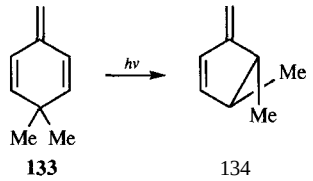
or $[(\pi\text{-allyl})PdCl]_2$[660] gives a mixture of the two dienes shown, resulting from a formal cleavage of the C_1-C_3 and C_1-C_2 bonds (note that a hydride shift has taken place).

18-39 *The Di-π-methane and Related Rearrangements*

DI-π-METHANE REARRANGEMENT

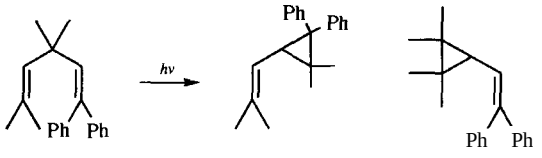


1,4-Dienes carrying alkyl or aryl substituents on C-3[661] can be photochemically rearranged to vinylcyclopropanes in a reaction called the *di-π-methane rearrangement*.[662] An example is conversion of 133 to 134.[663] For most 1,4-dienes, it is only



133 134

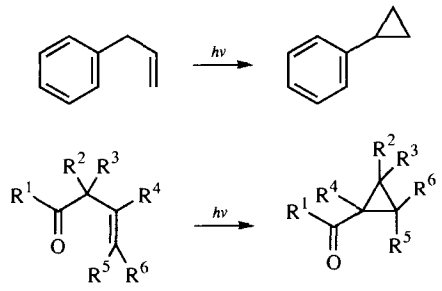
the singlet excited states that give the reaction; triplet states generally take other pathways.[664] For unsymmetrical dienes, the reaction is regioselective. For example, 135 gave 136, not **137**:[665]



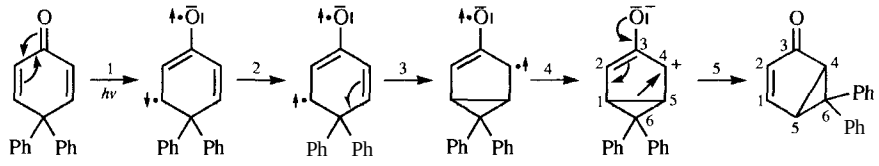
135 136 137
Not formed

The mechanism can be described by the diradical pathway given[666] (the C-3 substituents act to stabilize the radical), though the species shown are not necessarily intermediates, but may be transition states. It has been shown, for the case of certain substituted substrates, that configuration is retained at C-1 and C-5 and inverted at C-3.[667]

The reaction has been extended to allylic benzenes (in this case C-3 substituents are not required),[668] to β,γ-unsaturated ketones[669] (the latter reaction, which is called the *oxa-di-n-methane rearrangement,*[670] generally occurs only from the triplet state), to β,γ-unsaturated imines,[671] and to triple-bond systems.[672]



When photolyzed, 2,5-cyclohexadienones can undergo a number of different reactions, one of which is formally the same as the di-π-methane rearrangement.[673] In this reaction, photolysis of the substrate **138** gives the bicyclo[3.1.0]hexenone **(143).** Though the reaction is formally the same (note the conversion of **133** to **134**



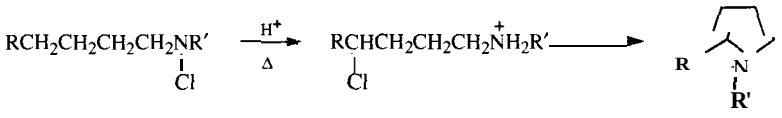
138 **139** Singlet 140 Triplet **141** Triplet 142 143

above), the mechanism is different from that of the di-n-methane rearrangement, because irradiation of a ketone can cause an $n \rightarrow n^*$ transition, which is of course not possible for a diene lacking a carbonyl group. The mechanism[674] in this case has been formulated as proceeding through the excited triplet states **140** and **141.** In step 1, the molecule undergoes an $n \rightarrow \pi^*$ excitation to the singlet species **139,** which cross to the triplet **140.** Step 3 is a rearrangement from one excited state to another. Step 4 is a $n^* \rightarrow n$ electron demotion (an intersystem crossing from $T_1 \rightarrow S_0$, see p. 315). The conversion of **142** to **143** consists of two 1,2 alkyl migrations (a one-

step process would be a 1,3 migration of alkyl to a carbocation center, see p. XXX): The old C_6–C_5 bond becomes the new C_6–C_4 bond and the old C_6–C_1 bond becomes the new C_6–C_5 bond.[675]

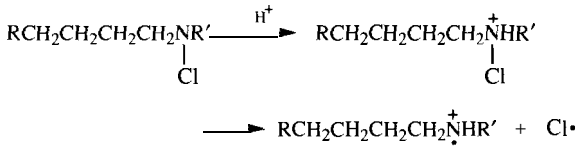
2,4-Cyclohexadienones also undergo photochemical rearrangements, but the products are different, generally involving ring opening.[676]

18-40 *The Hofmann–Löffler and Related Reactions*

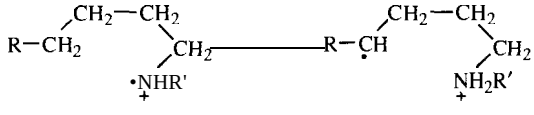


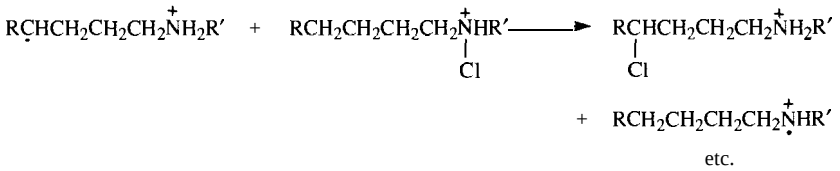
A common feature of the reactions in this section[677] is that they serve to introduce functionality at a position remote from functional groups already present. As such, they have proved very useful in synthesizing many compounds, especially in the steroid field (see also 19-2 and 19-14). When N-haloamines in which one alkyl group has a hydrogen in the 4 or 5 position are heated with sulfuric acid, pyrrolidines or piperidines are formed, in a reaction known as the *Hofmann-Loffler reaction* (also called the *Hofmann–Löffler–Freytag reaction*).[678] R' is normally alkyl, but the reaction has been extended to R' = H by the use of concentrated sulfuric acid solution and ferrous salts.[679] The first step of the reaction is a rearrangement, with the halogen migrating from the nitrogen to the 4 or 5 position of the alkyl group. It is possible to isolate the resulting haloamine salt, but usually this is not done, and the second step, the ring closure (10-44), takes place. Though the reaction is most often induced by heat, this is not necessary, and irradiation and chemical initiators (e.g., peroxides) have been used instead. The mechanism is of a free-radical type, with the main step involving an internal hydrogen abstraction.[680]

Initiation



Propagation



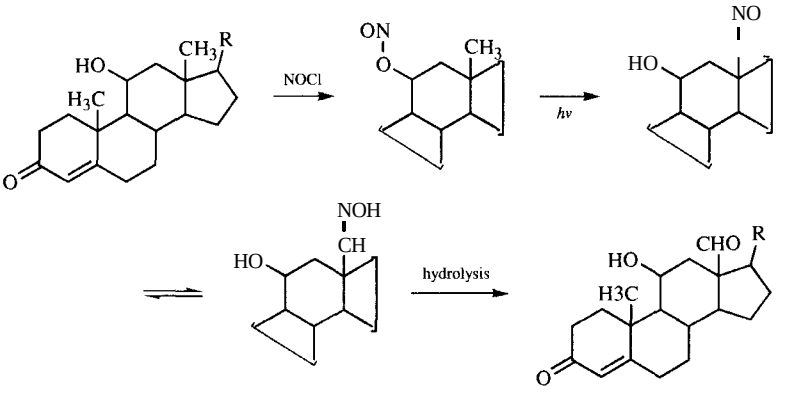


etc.

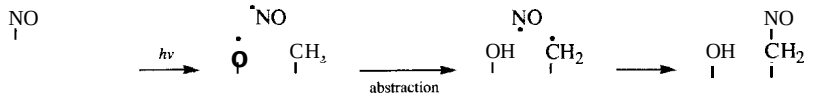
A similar reaction has been carried out on N-halo amides, which give γ-lactones:[681]

$$RCH_2CH_2CH_2CONHI \xrightarrow{h\nu} \underset{\underset{O-C=O}{|}}{RCHCH_2CH_2}$$

Another related reaction is the *Barton reaction*,[682] by which a methyl group in the 9 position to an OH group can be oxidized to a CHO group. The alcohol is first converted to the nitrite ester. Photolysis of the nitrite results in conversion of the nitrite group to the OH group and nitrosation of the methyl group. Hydrolysis of the oxime tautomer gives the aldehyde, for example,[683]



This reaction takes place only when the methyl group is in a favorable steric position.[684] The mechanism is similar to that of the Hofmann-Löffler reaction.[685]

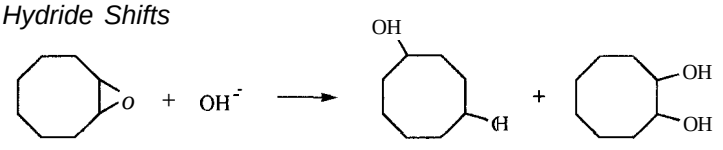


This is one of the few known methods for effecting substitution at an angular methyl group. Not only CH_3 groups but also alkyl groups of the form RCH_2 and R_2CH can give the Barton reaction if the geometry of the system is favorable. An RCH_2 group is converted to the oxime R(C=NOH) (which is hydrolyzable to a ketone) or to a nitroso dimer, while an R_2CH group gives a nitroso compound $R_2C(NO)$. With very few exceptions, the only carbons that become nitrosated are those in the position 5 to the original OH group, indicating that a six-membered transition state is necessary for the hydrogen abstraction.[686]

OS III, 159.

D. *Non-cyclic Rearrangements*

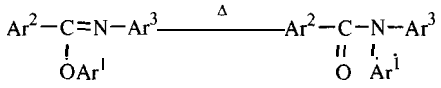
18-41 *Hydride Shifts*



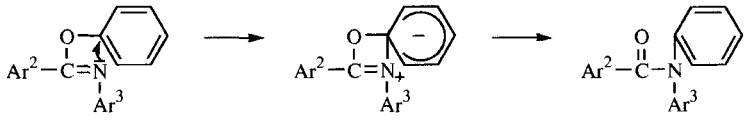
The above is a typical example of a transannular hydride shift. The 1,2-diol is formed by a normal epoxide hydrolysis reaction (10-7). For a discussion of 1,3 and longer hydride shifts, see page 1387.

18-42 *The Chapman Rearrangement*

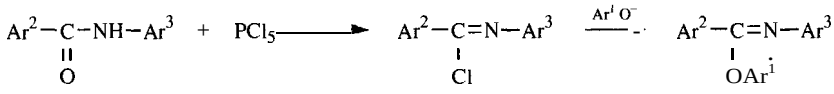
1/*O* → 3/*N*-ARYL-MIGRATION



In the *Chapman rearrangement,* N,N-diaryl amides are formed when aryl imino esters are heated.[687] Best yields are obtained in refluxing tetraethylene glycol dimethyl ether (tetraglyme),[688] though the reaction can also be carried out without any solvent at all. Many groups may be present in the rings (e.g., alkyl, halo, OR, CN, COOR). Aryl migrates best when it contains electron-withdrawing groups. On the other hand, electron-withdrawing groups in Ar^2 or Ar^3 decrease the reactivity. The products can be hydrolyzed to diarylamines, and this is a method for preparing

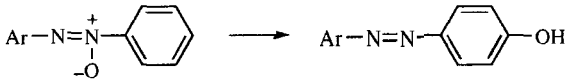


these compounds. The mechanism probably involves an intramolecular[689] aromatic nucleophilic substitution, resulting in a 1,3 oxygen-to-nitrogen shift. Aryl imino esters can be prepared from N-aryl amides by reaction with PC15, followed by treatment of the resulting imino chloride with an aroxide ion.[690]



Imino esters with any or all of the three groups being alkyl also rearrange, but they require catalysis by H_2SO_4 or a trace of methyl iodide or methyl sulfate.[691] The mechanism is different, involving an intermolecular process.[692] This is also true for derivatives for formamide (Ar^2 = H).

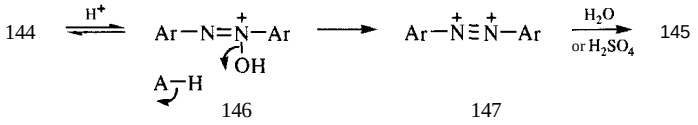
18-43 *The Wallach Rearrangement*



144 145

The conversion of azoxy compounds, (144) on acid treatment, to *p*-hydroxy azo compounds (145, or sometimes the o-hydroxy isomers[693]) is called the *Wallach rearrangement.*[694] When both para positions are occupied, the o-hydroxy product

may be obtained, but ipso substitution at one of the para positions is also possible.[695] Although the mechanism[696] is not completely settled, the following facts are known: (1) The para rearrangement is intermolecular.[697] (2) When the reaction was carried out with an azoxy compound in which the N—O nitrogen was labeled with ^{15}N, *both* nitrogens of the product carried the label equally,[698] demonstrating that the oxygen did not have a preference for migration to either the near or the far ring. This shows that there is a symmetrical intermediate. (3) Kinetic studies show that two protons are normally required for the reaction.[699] The following mechanism,[700] involving the symmetrical intermediate 147, has been proposed to explain the facts.[701]



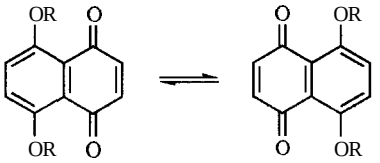
It has proved possible to obtain 146 and 147 as stable species in superacid solutions.[613] Another mechanism, involving an intermediate with only one positive charge, has been proposed for certain substrates at low acidities.[702]

A photochemical Wallach rearrangement[703] is also known: The product is the *o*-hydroxy azo compound, the OH group is found in the farther ring, and the rearrangement is intramolecular.[704]

18-44 *Dyotropic Rearrangements*

1/*C*-TRIALKYLSILYL,2/*O*-TRIALKYLSILYL-INTERCHANGE

A *dyotropic rearrangement*[705] is an uncatalyzed process in which two <7 bonds simultaneously migrate intramolecularly.[706] There are two types. The above is an example of type 1, which consists of reactions in which the two σ bonds interchange positions. In type 2, the two σ bonds do not interchange positions. An example is



Some other examples are

Type 1 $R-C\equiv\overset{+}{N}-\bar{O} \rightleftharpoons O=C=N-R$ Ref. 707

Nitrile oxide — Isocyanate

[440] Note that a [1,5] sigmatropic rearrangement of hydrogen is also an internal ene synthesis **(15-20).**

[441] Since we are using the arbitrary designations U, V, Y, and A, we have been arbitrary in which isomer to call (*R,Z*) and which to call (*S,E*).

[442] See Woodward, R.B.; Hoffmann, R. Ref. 438, p. 114.

[443] This follows from the principle that bonds are formed only by overlap of orbitals of the same sign. Since this is a concerted reaction, the hydrogen orbital in the transition state

must overlap simultaneously with one lobe from the migration origin and one from the terminus. It is obvious that both of these lobes must have the same sign.

[444] A possible [1,3] migration of hydrogen has been reported. See Yeh, M; Linder, L.; Hoffman, D.K.; Barton, T.J. *J. Am. Chem. Soc,* ***1986,*** *108,* 7849. See also Pasto, D.J.; Brophy, J.E. *J. Org. Chem.*, ***1991,*** *56,* 4554.

CHAPTER 19

Oxidations and Reductions

First, we must examine what we mean when we speak of oxidation and reduction. Inorganic chemists define oxidation in two ways: loss of electrons and increase in oxidation number. In organic chemistry, these definitions, while still technically correct, are not easy to apply. While electrons are directly transferred in some organic oxidations and reductions, the mechanisms of most of these reactions do not involve a direct electron transfer. As for oxidation number, while this is easy to apply in some cases, (e.g., the oxidation number of carbon in CH_4 is -4), in most cases attempts to apply the concept lead to fractional values or to apparent absurdities. Thus carbon in propane has an oxidation number of -2.67 and in butane of -2.5, though organic chemists seldom think of these two compounds as being in different oxidation states. An improvement could be made by assigning different oxidation states to different carbon atoms in a molecule, depending on what is bonded to them (e.g., the two carbons in acetic acid are obviously in different oxidation states), but for this a whole set of arbitrary assumptions would be required, since the oxidation number of an atom in a molecule is assigned on the basis of the oxidation numbers of the atoms attached to it. There would seem little to be gained by such a procedure. The practice in organic chemistry has been to set up a series of functional groups, in a qualitative way, arranged in order of increasing oxidation state, and then to define oxidation as *the conversion of a functional group in a molecule from one category to a higher one.* Reduction is the opposite. For the simple functional groups, this series is shown in Table 19.1.[1] It should be noted that this classification applies only to a single carbon atom or to two adjacent carbon atoms. Thus 1,3-dichloropropane is in the same oxidation state as chloromethane, but 1,2-dichloropropane is in a higher one. Obviously, such distinctions are somewhat arbitrary, and if we attempt to carry them too far, we shall find ourselves painted into a corner. Nevertheless, the basic idea has served organic chemistry well. It should be noted that conversion of any compound to another in the same category is not an oxidation or a reduction. Most oxidations in organic chemistry involve a gain of oxygen and/or a loss of hydrogen (Lavoisier's original definition of oxidation). The reverse is true for reductions.

Of course, there is no oxidation without a concurrent reduction. However, we classify reactions as oxidations or reductions depending on whether the *organic compound* is oxidized or reduced. In some cases both the oxidant and reductant are organic; those reactions are treated separately at the end of the chapter.

TABLE 19.1 Categories of Simple Functional Groups Arranged According to Oxidation State [a]

Approximate Oxidation Number				
-4	−2	0	+2	+4
RH				**CO_2**
	ROH **RC1**			**CCl_4**
	RNH_2			
				
	etc.		etc.	
		OH OH etc.		

[a] Oxidation is the conversion of a functional group in a molecule to a higher category; reduction is conversion to a lower one. Conversions within a category are neither oxidations nor reductions. The numbers given at the bottom are only approximations.

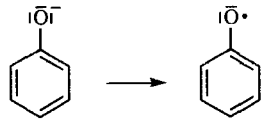
MECHANISMS

Note that our definition of oxidation has nothing to do with mechanism. Thus the conversion of bromomethane to methanol with KOH **(10-1)** and to methane with $LiAlH_4$ **(10-79)** have the same S_N2 mechanisms, but one is a reduction (according to our definition) and the other is not. It is impractical to consider the mechanisms of oxidation and reduction reactions in broad categories in this chapter as we have done for the reactions considered in Chapters 10-18.[2] The main reason is that the mechanisms are too diverse, and this in turn is because the bond changes are too different. For example, in Chapter 15, all the reactions involved the bond change C=C→ W—C—C—Y and a relatively few mechanisms covered all the reactions. But for oxidations and reductions the bond changes are far more diverse. Another reason is that the mechanism of a given oxidation or reduction reaction can vary greatly

with the oxidizing or reducing agent employed. Very often the mechanism has been studied intensively for only one or a few of many possible agents.

Though we therefore do not cover oxidation and reduction mechanisms in the same way as we have covered other mechanisms, it is still possible to list a few broad mechanistic categories. In doing this, we follow the scheme of Wiberg.[3]

1. *Direct Electron Transfer.*[4] We have already met some reactions in which the reduction is a direct gain of electrons or the oxidation a direct loss of them. An example is the Birch reduction (15-14), where sodium directly transfers an electron to an aromatic ring. An example from this chapter is found in the bimolecular reduction of ketones (19-55), where again it is a metal that supplies the electrons. This kind of mechanism is found largely in three types of reaction:[5] (a) the oxidation or reduction of a free radical (oxidation to a positive or reduction to a negative ion), (b) the oxidation of a negative ion or the reduction of a positive ion to a comparatively stable free radical, and (c) electrolytic oxidations or reductions (an example is the Kolbe reaction, 14-36). An important example of (b) is oxidation of amines and phenolate ions:



These reactions occur easily because of the relative stability of the radicals involved.[6] The SET mechanism, which we have met several times (e.g., p. 402) is an important case.

2. *Hydride Transfer.*[7] In some reactions, a hydride ion is transferred to or from the substrate. The reduction of epoxides with $LiAlH_4$ is an example (10-85). Another is the Cannizzaro reaction (19-60). Reactions in which a carbocation abstracts a hydride ion belong in this category:[8]

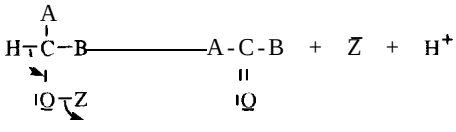
$$R^+ + R'H \longrightarrow RH + R'^+$$

3. *Hydrogen-Atom Transfer.* Many oxidation and reduction reactions are free-radical substitutions and involve the transfer of a hydrogen atom. For example, one of the two main propagation steps of 14-1 involves abstraction of hydrogen:

$$RH + Cl\cdot \longrightarrow R\cdot + HCl$$

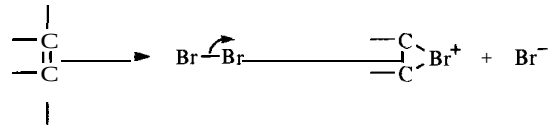
This is the case for many of the reactions of Chapter 14.

4. *Formation of Ester Intermediates.* A number of oxidations involve the formation of an ester intermediate (usually of an inorganic acid), and then the cleavage of this intermediate:

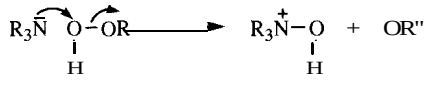


Z is usually CrO_3H, MnO_3, or a similar inorganic acid moiety. One example of this mechanism was seen in **14-6,** where A was an alkyl or aryl group, B was OH, and Z was CrO_3H. Another is the oxidation of a secondary alcohol to a ketone (19-3), where A and B are alkyl or aryl groups and Z is also CrO_3H. In the lead tetraacetate oxidation of glycols **(19-7)** the mechanism also follows this pattern, but the positive leaving group is carbon instead of hydrogen. It should be noted that the cleavage shown is an example of an E2 elimination.

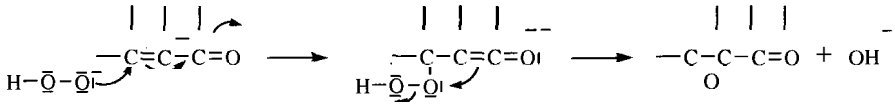
5. *Displacement Mechanisms.* In these reactions the organic substrate uses its electrons to cause displacement on an electrophilic oxidizing agent. One example is the addition of bromine to an alkene **(15-37).**



An example from this chapter is found in **19-27:**



6. *Addition-Elimination Mechanisms.* In the reaction between α,β-unsaturated ketones and alkaline peroxide **(15-48),** the oxidizing agent adds to the substrate, and then part of it is lost:



In this case, the oxygen of the oxidizing agent is in oxidation state − 1 and the OH^- departs with its oxygen in the — 2 state, so it is reduced and the substrate oxidized. There are several reactions that follow this pattern of addition of an oxidizing agent and the loss of part of the agent, usually in a different oxidation state. Another example is the oxidation of ketones with SeO_2 (19-14). This reaction is also an example of category 4, since it involves formation and E2 cleavage of an ester. This example shows that these six categories are not mutually exclusive.

REACTIONS

In this chapter, the reactions are classified by the type of bond change occurring to the organic substrate, in conformity with our practice in the other chapters.[9] This means that there is no discussion in any one place of the use of a particular oxidizing or reducing agent, for example, acid dichromate or $LiAlH_4$ (except for a discussion of selectivity of reducing agents, p. 1544). Some oxidizing or reducing agents are

fairly specific in their action, attacking only one or a few types of substrate. Others, like acid dichromate, permanganate, $LiAlH_4$, and catalytic hydrogenation, are much more versatile.[10]

When an oxidation or a reduction could be considered in a previous chapter, this was done. For example, the catalytic hydrogenation of alkenes is a reduction, but it is also an addition to the C=C bond and was treated in Chapter 15. This chapter discusses only those reactions that do not fit into the nine categories of Chapters 10-18. An exception to this rule was made for reactions that involve elimination of hydrogen (19-1-19-6), which were not treated in Chapter 17 because the mechanisms generally differ from those in that chapter.

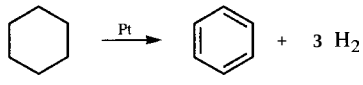
Oxidations[11]

The reactions in this section are classified into groups depending on the type of bond change involved. These groups are (A) eliminations of hydrogen, (B) reactions involving cleavage of carbon-carbon bonds, (C) reactions involving replacement of hydrogen by oxygen, (D) reactions in which oxygen is added to the substrate, and (E) oxidative coupling.

A. *Eliminations of Hydrogen*

19-1 *Aromatization of Six-Membered Rings*

HEXAHYDRO-TERELIMINATION



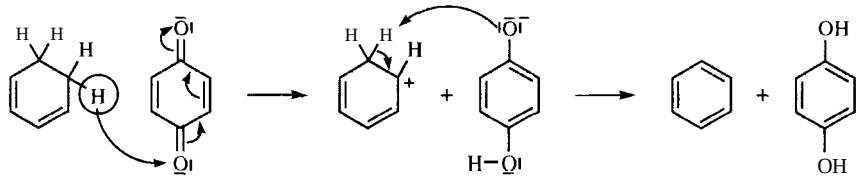
Six-membered alicyclic rings can be aromatized in a number of ways.[12] Aromatization is accomplished most easily if there are already one or two double bonds in the ring or if the ring is fused to an aromatic ring. The reaction can also be applied to heterocyclic five- and six-membered rings. Many groups may be present on the ring without interference, and even *gem*-dialkyl substitution does not always prevent the reaction: In such cases, one alkyl group often migrates or is eliminated. However, more drastic conditions are usually required for this. In some cases, OH and COOH groups are lost from the ring. Cyclic ketones are converted to phenols. Seven-membered and larger rings are often isomerized to six-membered aromatic rings, though this is not the case for partially hydrogenated azulene systems, which are frequently found in nature; these are converted to azulenes.

There are three types of reagents most frequently used to effect aromatization.

1. Hydrogenation catalysts,[13] such as platinum, palladium, nickel, and so on. In this case the reaction is the reverse of double-bond hydrogenation (15-11 and 15-15), and presumably the mechanism is also the reverse, though not much is known.[14] Cyclohexene has been detected as an intermediate in the conversion

of cyclohexane to benzene, using Pt.[15] The substrate is heated with the catalyst at ~300–350°C. The reactions can often be carried out under milder conditions if a hydrogen acceptor, such as maleic acid, cyclohexene, or benzene, is present to remove hydrogen as it is formed. The acceptor is reduced to the saturated compound. It has been reported that dehydrogenation of 1-methylcyclohexene-1-^{13}C over an alumina catalyst gave toluene with the label partially scrambled throughout the aromatic ring.[16]

2. The elements sulfur and selenium, which combine with the hydrogen evolved to give, respectively, H_2S and H_2Se. Little is known about this mechanism either.[17]
3. Quinones,[18] which become reduced to the corresponding hydroquinones. Two important quinones often used for aromatizations are chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone) and DDQ (2,3-dichloro-5,6-dicyano-1,4-benzoquinone).[19] The latter is more reactive and can be used in cases where the substrate is difficult to dehydrogenate. It is likely that the mechanism involves a transfer of hydride to the quinone oxygen, followed by the transfer of a proton to the phenolate ion:[20]



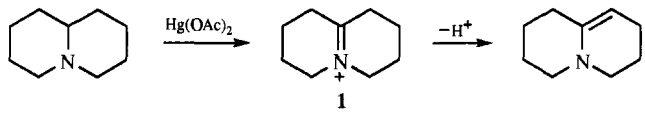
Among other reagents[21] that have been used are atmospheric oxygen, MnO_2,[22] SeO_2, various strong bases,[23] chromic acid,[24] and SeO_2 on P_2O_5/$Me_3SiOSiMe_3$.[25] The last-mentioned reagent also dehydrogenates cyclopentanes to cyclopentadienes. In some instances, the hydrogen is not released as H_2 or transferred to an external oxidizing agent but instead serves to reduce another molecule of substrate. This is a disproportionation reaction and can be illustrated by the conversion of cyclohexene to cyclohexane and benzene.

Heteroatom rings, such as that found in quinoline derivatives, can be generated from amino-ketones with [hydroxy(tosyloxy)iodo]benzene and perchloric acid.[26] Cyclic imines are converted to pyridine derivatives with NCS and then excess sodium methoxide.[27]

OS II, 214, 423; III, 310, 358, 729, 807; IV, 536; VI, 731. Also see OS III, 329.

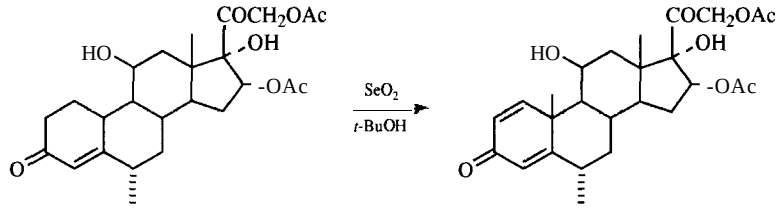
19-2 *Dehydrogenations Yielding Carbon-Carbon Double Bonds*

DIHYDRO-ELIMINATION



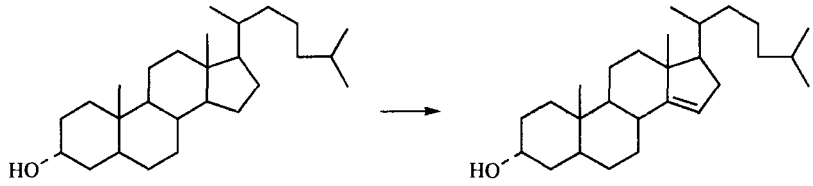
1

Dehydrogenation of an aliphatic compound to give a double bond in a specific location is not usually a feasible process, though industrially mixtures of alkenes are obtained in this way from mixtures of alkanes (generally by heating with chromia–alumina catalysts). There are, however, some notable exceptions, and it is not surprising that these generally involve cases where the new double bond can be in conjugation with a double bond or with an unshared pair of electrons already present.[28] One example is the synthesis developed by Leonard and co-workers,[29] in which tertiary amines give enamines when treated with mercuric acetate[30] (see the example above). In this case, the initial product is the iminium ion (1), which loses a proton to give the enamine. In another example, the oxidizing agent SeO_2 can in certain cases convert a carbonyl compound to an α,β-unsaturated carbonyl compound by removing H_2 (though this reagent more often gives 19-14).[31] This reaction has been most often applied in the steroid series, an example being[32]



Similarly, SeO_2 has been used to dehydrogenate 1,4-diketones ($RCOCH_2CH_2COR \rightarrow RCOCH{=}CHCOR$)[33] and 1,2-diarylalkanes ($ArCH_2CH_2Ar \rightarrow ArCH{=}CHAr$). These conversions can also be carried out by certain quinones, most notably DDQ (see **19-1**).[19] Ketones have been converted to conjugated ketones with Ph(S=O)OMe and KH[34] and also with (pyridyl)S(=O)OMe/KH, and then $CuSO_4$.[35] Silyl enol ethers also give the conjugated ketone upon treatment with ceric ammonium nitrate in DMF[36] or with $Pd(OAc)_2/NaOAc/O_2$.[37] Simple aldehydes and ketones have been dehydrogenated (e.g., cyclopentanone → cyclopentenone) by $PdCl_2$,[38] by $FeCl_3$,[39] and by benzeneseleninic anhydride (this reagent also dehydrogenates lactones in a similar manner),[40] among other reagents.

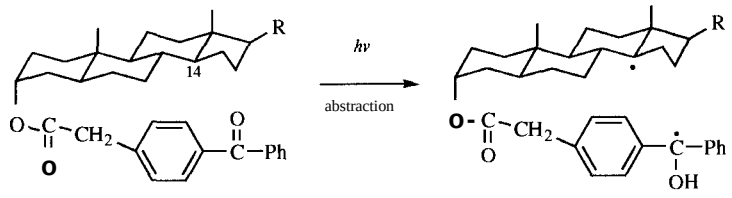
In an indirect method of achieving this conversion, the silyl enol ether of a simple ketone is treated with DDQ[41] or with triphenylmethyl cation (for another indirect method, see 17-11).[42] Simple linear alkanes have been converted to alkenes by treatment with certain transition metal compounds.[43]



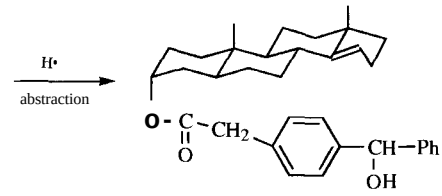
2 3

An entirely different approach to specific dehydrogenation has been reported by. Breslow[44] and by J.E. Baldwin.[45] By means of this approach it was possible, for example, to convert 3α-cholestanol (2) to 5α-cholest-14-en-3α-ol (3), thus intro-

ducing a double bond at a specific site remote from any functional group.[46] This was accomplished by conversion of 2 to the ester (4), followed by irradiation of 4, which gave 55% 6, which was then hydrolyzed to 3. The radiation excites the benzo-

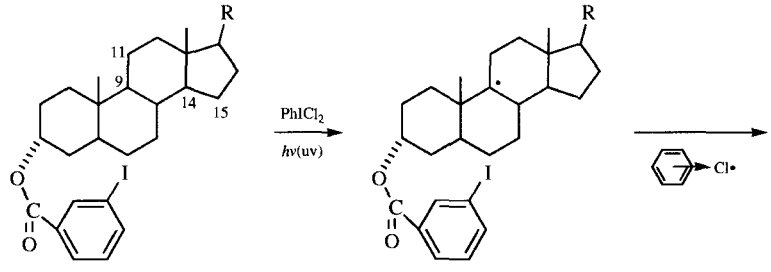


4 5

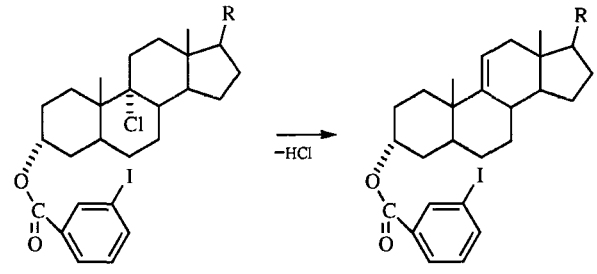


6

phenone portion of 4 (p. 321), which then abstracts hydrogen from the 14 position to give the diradical 5, which undergoes another internal abstraction to give 6. In other cases, diradicals like 5 can close to a macrocyclic lactone **(19-14).** In an alternate approach,[47] a 9(11) double bond was introduced into a steroid nucleus by



7



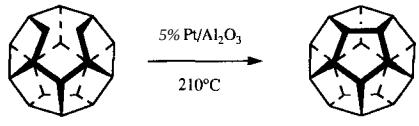
8 9

reaction of the *m*-iodo ester (7) with $PhICl_2$ and UV light, which results in hydrogen being abstracted regioselectively from the 9 position, resulting in chlorination at that position. Dehydrohalogenation of 8 gives the 9(11)-unsaturated steroid **(9).** In

contrast, use of the para isomer of 7 results in chlorination at the 14 position and loss of HC1 gives the 14-unsaturated steroid. These reactions are among the very few ways to introduce functionality at a specific site remote from any functional group (see also **19-14).**

Certain 1,2-diarylalkenes ArCH=CHAr′ have been converted to the corresponding alkynes ArC≡CAr'by treatment with *t*-BuOK in DMF.[48]

A different kind of dehydrogenation was used in the final step of Paquette's synthesis of dodecahedrane:[49]



Dodecahedrane

OS V, 428, **VII,** 4, 473.

19-3 *Oxidation or Dehydrogenation of Alcohols to Aldehydes and Ketones*

C,O-DIHYDRO-ELIMINATION

$$RCH_2OH \xrightarrow[chromite]{copper} RCHO$$

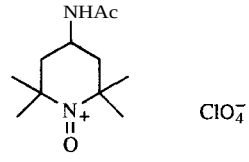
$$RCHOHR' \xrightarrow[H_2SO_4]{K_2Cr_2O_7} RCOR'$$

Primary alcohols can be converted to aldehydes and secondary alcohols to ketones in five main ways:'

1. *With Strong Oxidizing Agents.*[51] Secondary alcohols are easily oxidized to ketones by acid dichromate[52] at room temperature or slightly above. Though this is the most common reagent, many other strong oxidizing agents (e.g., $KMnO_4$, Br_2, MnO_2,[53] ruthenium tetroxide,[54] etc.) have also been employed. A solution of chromic acid and sulfuric acid in water is known as the *Jones reagent.*[55] When secondary alcohols are dissolved in acetone, titration with the Jones reagent oxidizes them to ketones rapidly and in high yield without disturbing any double or triple bonds that may be present (see **19-10)** and without epimerizing an adjacent chiral center.[56] The Jones reagent also oxidizes primary allylic alcohols to the corresponding aldehydes.[57] Three other Cr(VI) reagents commonly used[58] are dipyridine Cr(VI) oxide *(Collins' reagent),*[59] pyridinium chlorochromate,[60] and pyridinium dichromate[61] MnO_2 is also a fairly specific reagent for OH groups and is often used to oxidize allylic alcohols to α,β-unsaturated aldehydes or ketones. For acid-sensitive

compounds CrO_3 in HMPA[62] or trimethylsilyl chromates[63] can be used. Sodium hypochlorite in acetic acid is useful for oxidizing larger amounts of secondary alcohols.[64] The oxidizing agent can be supported on a polymer.[65] Both chromic acid[66] and permanganate[67] have been used in this way (see p. 509). Phase-transfer catalysis has also been used with permanganate,[68] chromic acid,[69] and ruthenium tetroxide.[70] Phase-transfer catalysis is particularly useful because the oxidizing agents are insoluble in most organic solvents, while the substrates are generally insoluble in water (see p. 454). Ultrasound has been used for $KMnO_4$ oxidations.[71]

Most of these oxidizing agents have also been used to convert primary alcohols to aldehydes, but precautions must be taken that the aldehyde is not further oxidized to the carboxylic acid (19-21).[72] One way to halt oxidation is by distillation of the aldehyde as it is formed. The following are among the oxidizing agents that have been used to convert at least some primary alcohols to aldehydes:[73] DMSO (see **19-19),** Collins' reagent, Corey's reagent, pyridinium dichromate, $Na_2Cr_2O_7$ in water,[74] $K_2Cr_2O_7$ in DMF at 100°C,[75] CrO_3 on silica gel,[76] wet CrO_3 on alumina with microwave irradiation,[77] tetrapropylammonium perruthenate ($Pr_4N^+ RuO_4^-$; also called TPAP),[78] and NCS-TEMPO.[79] Other nitroxyl radical oxidizing agents are known.[80] A related



10

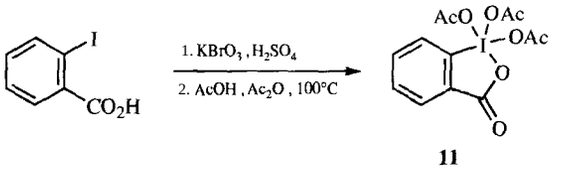
oxidizing agent is oxoammonium salt (10), a stable and nonhygroscopic salt that oxidizes primary and secondary alcohols in dichloromethane.[81] Most of these reagents also oxidize secondary alcohols to ketones. Reagents that can be used specifically to oxidize a secondary OH group in the presence of a primary OH group[82] are H_2O_2–ammonium molybdate,[83] $NaBrO_3$–CAN,[84] and NaOCl in HOAc,[85] while $RuCl_2(PPh_3)_3$–benzene,[86] osmium tetroxide,[87] and Br_2–$Ni(OBz)_2$[88] oxidize primary OH groups in the presence of a secondary OH group.[89] Benzylic and allylic alcohols have been selectively oxidized to the aldehydes in the presence of saturated alcohols by the use of potassium manganate ($KMnO_4$) under phase-transfer conditions.[90] On the other hand, Fremy's salt (see **19-4)** selectively oxidizes benzylic alcohols and not allylic or saturated ones.[91] Certain zirconocene complexes can selectively oxidize only one OH group of a diol, even if both are primary.[92]

2. *By Catalytic Dehydrogenation.* For the conversion of primary alcohols to aldehydes, dehydrogenation catalysts have the advantage over strong oxidizing agents that further oxidation to the carboxylic acid is prevented. Copper chromite is the agent most often used, but other catalysts (e.g., silver and copper) have also been employed. Many ketones have also been prepared

in this manner. Catalytic dehydrogenation is more often used industrially than as a laboratory method. However, convenient laboratory procedures using copper oxide,[93] Raney nickel,[94] and palladium acetate (under phase-transfer conditions)[95] have been reported.

3. *The Oppenauer Oxidation.* When a ketone in the presence of base is used as the oxidizing agent (it is reduced to a secondary alcohol), the reaction is known as the *Oppenauer oxidation.*[96] This is the reverse of the Meerwein-Ponndorf-Verley reaction **(16-23),** and the mechanism is also the reverse. The ketones most commonly used are acetone, butanone, and cyclohexanone. The most common base is aluminum tert-butoxide. The chief advantage of the method is its high selectivity. Although the method is most often used for the preparation of ketones, it has also been used for aldehydes.
4. *With DMSO Based Reagents.* An alcohol is treated with DMSO, DCC,[97] and anhydrous phosphoric acid[98] in what is called *Moffatt oxidation.* In this way, a primary alcohol can be converted to the aldehyde with no carboxylic acid being produced.

   Similar oxidation of alcohols has been carried out with DMSO and other reagents[99] in place of DCC: acetic anhydride,[100] SO_3–pyridine–triethylamine,[101] trifluoroacetic anhydride,[102] oxalyl chloride (called *Swern oxidation*)[103] tosyl chloride,[104] P_2O_5-Et_3N,[105] trichloromethyl chloroformate,[106] trimethylamine *N*-oxide,[107] KI and $NaHCO_3$,[108] and methanesulfonic anhydride,[322] among others.
5. *With Hypervalent Iodine Reagents.* Treatment of 2-iodobenzoic acid with $KBrO_3$ in sulfuric acid and heating the resulting product to 100°C with acetic anhydride and acetic acid gives hypervalent iodine reagent (11), the so-called *Dess–Martin Periodinane.*[109] This reagent reacts with alcohols at ambient temperature to give the corresponding aldehyde or ketone.[110] The reaction is accelerated by water.[111]



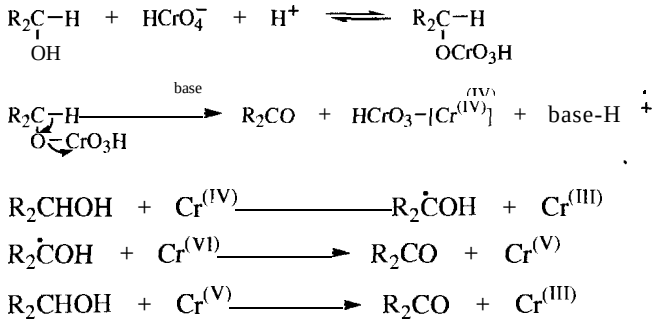
11

The reagent has an indefinite shelf-life in a sealed container but hydrolysis occurs upon long-term exposure to atmospheric moisture. A note of caution! The Dess-Martin reagent can be shock sensitive under some conditions and explode >200°C.[112] Other hypervalent iodine oxidizing reagents are known,[113] including $PhI(OAc)_2$/TEMPO[114] and $PhI(OAc)_2$ supported on alumina with microwave irradiation.[115]

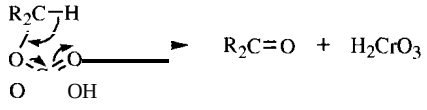
Primary and secondary alcohols can also be oxidized, indirectly, through their esters (see **19-20).** In some cases, isolation of the ester is not required and the alcohol can then be oxidized to the aldehyde or ketone in one step.

Enzymatic oxidations have been reported. *Bacilus stearothermophilus,* for example, oxidizes secondary alcohols to the ketone.[116]

The mechanism of oxidation with acid dichromate has been intensely studied.[117] The currently accepted mechanism is essentially that proposed by Westheimer.[118] The first two steps constitute an example of category 4 (p. 1508).



The base in the second step may be water, though it is also possible[119] that in some cases no external base is involved and that the proton is transferred directly to one of the CrO_3H oxygens in which case the Cr(IV) species produced would be H_2CrO_3.



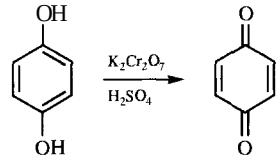
Part of the evidence for this mechanism was the isotope effect of ~6 found on use of MeCDOHMe, showing that the a hydrogen is removed in the rate-determining step.[120] Note that, as in 14-6, the substrate is oxidized by three different oxidation states of chromium.[121]

With other oxidizing agents, mechanisms are less clear.[122] It seems certain that some oxidizing agents operate by a hydride-shift mechanism,[173] for example, dehydrogenation with triphenylmethyl cation[124] and the Oppenauer oxidation, and some by a free-radical mechanism, for example, oxidation with $S_2O_8^{2-}$[125] and with VO_2^+.[126] A summary of many proposed mechanisms is given by Littler.[127]

OS I, 87, 211, 241, 340; II, 139, 541; III, 37, 207; IV, 189, 192, 195, 467, 813, 838; V, 242, 310, 324, 692, 852, 866; VI, 218, 220, 373, 644, 1033; VII, 102, 112, 114, 177, 258, 297; VIII, 43, 367, 386; IX, 132, 432. Also see OS IV, 283; VIII, 363, 501.

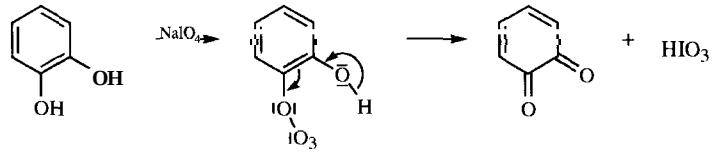
19-4 *Oxidation of Phenols and Aromatic Amines to Quinones*

1/*O*,6/*O*-Dihydro-elimination



Ortho and para diols are easily oxidized to ortho- and para-quinones, respectively.[128] Either or both OH groups can be replaced by NH_2 groups to give the same products, though for the preparation of ortho-quinones only OH groups are normally satisfactory. The reaction has been successfully carried out with other groups para to OH or NH_2; halogen, OR, Me, r-Bu, and even H, though with the last yields are poor. Many oxidizing agents have been used: acid dichromate,[129] silver oxide, silver carbonate, lead tetraacetate, HIO_4, dimethyl dioxirane,[130] and atmospheric oxygen,[131] to name a few. A particularly effective reagent for rings with only one OH or NH_2 group is $(KSO_3)_2N{-}O\cdot$ (dipotassium nitrosodisulfonate; *Fremy's salt),* which is a stable free radical.[132] Phenols, even some whose para positions are unoccupied, can be oxidized to ortho-quinones with diphenylseleninic anhydride.[133]

Less is known about the mechanism than is the case for **19-3**, but, as in that case, it seems to vary with the oxidizing agent. For oxidation of catechol with $NaIO_4$, it was found that the reaction conducted in $H_2{}^{18}O$ gave unlabeled quinone,[134] so the following mechanism[135] was proposed:



When catechol was oxidized with MnO_4^- under aprotic conditions, a semiquinone radical ion intermediate was involved.[136] For autoxidations[137] (i.e., with atmospheric oxygen) a free-radical mechanism is known to operate.[138]

OS I, 383, 482, 511; II, 175, 254, 430, 553; III, 663, 753; IV, 148; VI, 412, 480, 1010.

19-5 *Dehydrogenation of Amines*

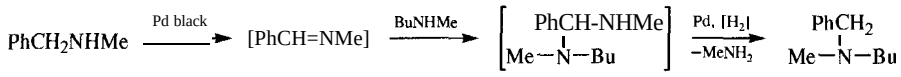
1/1/*N*,2/2/*C*-TETRAHYDRO-BIELIMINATION

$$RCH_2NH_2 \xrightarrow[2.\ H_2O]{1.\ NaOCl} RCN$$

Primary amines at a primary carbon can be dehydrogenated to nitriles. The reaction has been carried out with a variety of reagents, among others, lead tetraacetate,[139] NaOCl,[140] $K_2S_2O_8{-}NiSO_4$,[141] and $CuCl{-}O_2{-}$pyridine.[142] Several methods have been reported for the dehydrogenation of secondary amines to imines.[143] Among them[144] are treatment with (1) iodosylbenzene PhIO alone or in the presence of a ruthenium complex,[145] (2) Me_2SO and oxalyl chloride,[146] and (3) *t*-BuOOH and a rhenium catalyst.[147]

A reaction that involves dehydrogenation to an imine, which then reacts further is the reaction of primary or secondary amines[148] with palladium black.[149] The imine initially formed by the dehydrogenation reacts with another molecule of the same or a different amine to give an aminal, which loses NH_3 or RNH_2 to give a secondary or tertiary amine. An example is the reaction between *N*-methylbenzylamine and

butylmethylamine, which produces 95% *N*-methyl-*N*-butylbenzylamine.



19-6 *Oxidation of Hydrazines, Hydrazones, and Hydroxylamines*

1 / *N,2* / *N*-DIHYDRO-ELIMINATION

$$Ar\text{-}NH\text{-}NH\text{-}Ar \xrightarrow{NaOBr} Ar\text{-}N{=}N\text{-}Ar$$

N,N'-Diarylhydrazines (hydrazo compounds) are oxidized to azo compounds by several oxidizing agents, including NaOBr, HgO,[150] $K_3Fe(CN)_6$ under phase-transfer conditions,[151] MnO_2 (this reagent yields cis azobenzenes),[152] $CuCl_2$, and air and NaOH.[153] The reaction is also applicable to N,N'-dialkyl- and N,N'-diacylhydrazines. Hydrazines (both alkyl and aryl) substituted on only one side also give azo compounds,[154] but these are unstable and decompose to nitrogen and the hydrocarbon:

$$Ar{-}NH{-}NH_2 \longrightarrow [Ar{-}N{=}NH] \longrightarrow ArH + N_2$$

When hydrazones are oxidized with HgO, Ag_2O, MnO_2, lead tetraacetate, or certain other oxidizing agents, diazo compounds are obtained:[155]

$$R_2C{=}N{-}NH_2 \xrightarrow{HgO} R_2C{=}\overset{+}{N}{=}\overset{-}{N}$$

Hydrazones of the form $ArCH{=}NNH_2$ react with HgO in solvents such as diglyme or ethanol to give nitriles (ArCN).[156] Aromatic hydroxylamines (Ar—NH—OH) are easily oxidized to nitroso compounds (Ar—N=O), most commonly by acid dichromate.[157]

It is possible to oxidize dimethylhydrazones R—C=N—NMe_2 to the corresponding nitrile (R—C≡N) with $MeReO_3/H_2O_2$[158] magnesium monoperoxyphthalate (MMPP),[159] or with dimethyl dioxirane.[160]

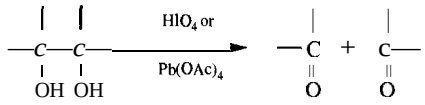
In a related reaction, primary aromatic amines have been oxidized to azo compounds by a variety of oxidizing agents, among them MnO_2, lead tetraacetate, O_2 and a base, barium permanganate,[161] and sodium perborate in acetic acid. *tert*-Butyl hydroperoxide has been used to oxidize certain primary amines to azoxy compounds.[162]

OS II, 496; **III,** 351, 356, 375, 668; IV, 66, 411; V, 96, 160, 897; VI, 78, 161, 334, 392, 803, 936; **VII,** 56. Also see OS V, 258. For oxidation of primary amines, see OS V, 341.

B. *Oxidations Involving Cleavage of Carbon-Carbon Bonds*[163]

19-7 *Oxidative Cleavage of Glycols and Related Compounds*

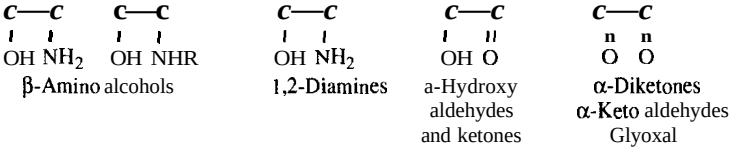
2/ *O*-DE-HYDROGEN-UNCOUPLING



1,2-Glycols are easily cleaved under mild conditions and in good yield with periodic acid or lead tetraacetate.[164] The products are 2 mol of aldehyde, or 2 mol of ketone, or 1 mol of each, depending on the groups attached to the two carbons. The yields are so good that alkenes are often converted to glycols (15-46), and then cleaved with HIO_4 or $Pb(OAc)_4$ rather than being cleaved directly with ozone (19-9) or dichromate or permanganate (19-10). A number of other oxidizing agents also give the same products, among them[165] activated MnO_2,[166] and pyridinium chlorochromate.[167] Permanganate, dichromate, and several other oxidizing agents[168] also cleave glycols, giving carboxylic acids rather than aldehydes, but these reagents are seldom used synthetically. Electrochemical oxidation is an efficient method, and is useful not only for diols, but also for their mono- and dimethoxy derivatives.[169]

The two reagents (periodic acid and lead tetraacetate) are complementary, since periodic acid is best used in water and lead tetraacetate in organic solvents. When three or more OH groups are located on adjacent carbons, the middle one (or ones) is converted to formic acid.

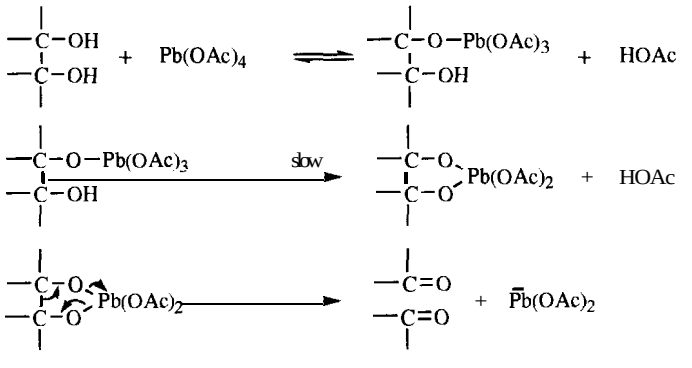
Similar cleavage is undergone by other compounds that contain oxygens or nitrogens on adjacent carbons:



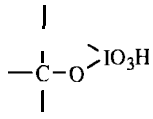
Cyclic 1,2-diamines are cleaved to diketones with dimethyl dioxirane.[170] α-Diketones and α-hydroxy ketones are also cleaved by alkaline H_2O_2.[171] HIO_4 has been used to cleave epoxides to aldehydes,[172] for example,

α-Hydroxy acids and α-keto acids are not cleaved by HIO_4 but are cleaved by $NaIO_4$ in methanol in the presence of a crown ether,[173] $Pb(OAc)_4$, alkaline H_2O_2, and other reagents. These are oxidative decarboxylations. a-Hydroxy acids give aldehydes or ketones, and a-keto acids give carboxylic acids. Also see 19-12 and 19-13.

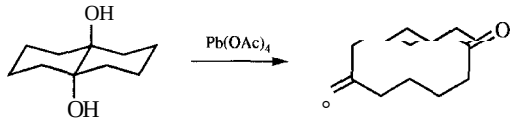
The mechanism of glycol oxidation with $Pb(OAc)_4$ was proposed by Criegee:[174]



This mechanism is supported by these facts: (1) the kinetics are second order (first order in each reactant); (2) added acetic acid retards the reaction (drives the equilibrium to the left); and (3) cis glycols react much more rapidly than trans glycols.[175] For periodic acid the mechanism is similar, with the intermediate[176]

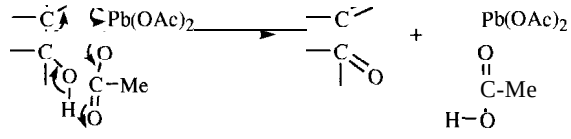


However, the cyclic-intermediate mechanism cannot account for all glycol oxidations, since some glycols that cannot form such an ester (e.g., 12) are nevertheless cleaved by lead tetraacetate



12

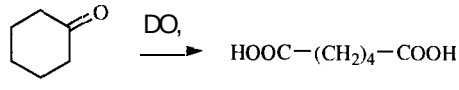
(though other glycols that cannot form cyclic esters are *not* cleaved, by either reagent[177]). To account for cases like 12, a cyclic transition state has been proposed:[175]



OS IV, 124; VII, 185; VIII, 396.

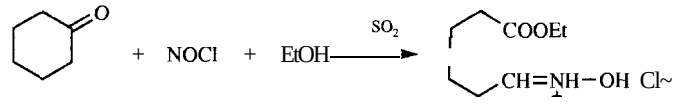
19-8 *Oxidative Cleavage of Ketones, Aldehydes, and Alcohols*

CYCLOALKANONE OXIDATIVE RING OPENING

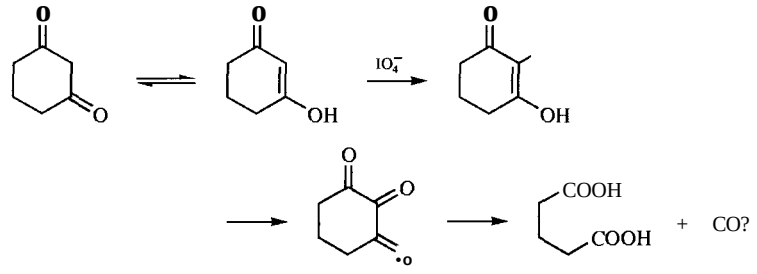


Oxidative cleavage of open-chain ketones or alcohols[178] is seldom a useful preparative procedure, not because these compounds do not undergo oxidation (they do, except for diaryl ketones) but because the result is generally a hopeless mixture. However, the reaction is quite useful for cyclic ketones and the corresponding secondary alcohols, the dicarboxylic acid being prepared in good yield. The formation of adipic acid from cyclohexanone (shown above) is an important industrial procedure. Acid dichromate and permanganate are the most common oxidizing agents, though autoxidation (oxidation with atmospheric oxygen) in alkaline solution[179] and potassium superoxide under phase-transfer conditions[180] have also been used. Other reagents include LiOCl/Chlorox®[181] and $MeOCO_2Me$ at 195°C.[182] Silyl-ketones have been cleaved to esters using electrolysis in alcohol solvents.[183]

Cyclic ketones can also be cleaved by treatment with NOCl and an alcohol in liquid SO_2 to give an ω-oximinocarboxylic ester, for example,[184]



Cyclic 1,3-diketones, which exist mainly in the monoenolic form, can be cleaved with sodium periodate with loss of one carbon, for example,[185]

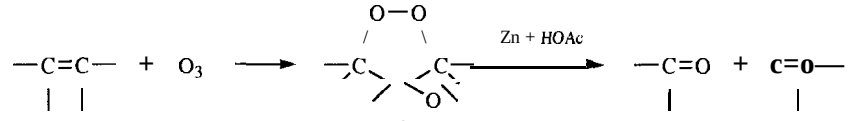


The species actually undergoing the cleavage is the triketone, so this is an example of 19-7.

OS I, 18; IV, 19; VI, 690. See also OS VI, 1024.

19-9 *Ozonolysis*

OXO-UNCOUPLING

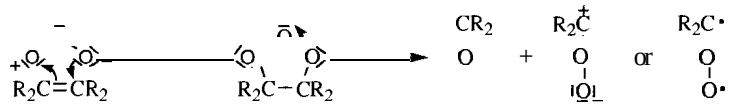


13

When compounds containing double bonds are treated with ozone, usually at low temperatures, they are converted to compounds called *ozonides* (13) that can be isolated but, because some of them are explosive, are more often decomposed with zinc and acetic acid or catalytic hydrogenation to give 2 mol of aldehyde, or 2 mol of ketone, or 1 mol of each, depending on the groups attached to the alkene.[186] The decomposition of 13 has also been carried out with triethylamine[187] and with reducing agents, among them trimethyl phosphite,[188] thiourea,[189] and dimethyl sulfide.[190] However, ozonides can also be *oxidized* with oxygen, peroxyacids, or H_2O_2 to give ketones and/or carboxylic acids or *reduced* with $LiAlH_4$, $NaBH_4$, BH_3, or catalytic hydrogenation with excess H_2 to give 2 mol of alcohol.[191] Ozonides can also be treated with ammonia, hydrogen, and a catalyst to give the corresponding amines,[192] or with an alcohol and anhydrous HC1 to give the corresponding carboxylic esters.[193] Ozonolysis is therefore an important synthetic reaction.

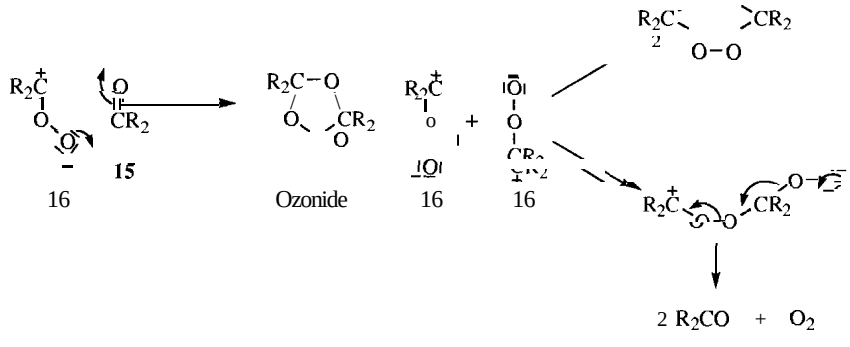
A wide variety of alkenes undergo ozonolysis, including cyclic ones, where cleavage gives rise to one bifunctional product. Alkenes in which the double bond is connected to electron-donating groups react many times faster than those in which it is connected to electron-withdrawing groups.[194] The reaction has often been carried

out on compounds containing more than one double bond; generally all the bonds are cleaved. In some cases, especially when bulky groups are present, conversion of the substrate to an epoxide **(15-48)** becomes an important side reaction and can be the main reaction.[195] Ozonolysis of triple bonds[196] is less common and the reaction proceeds less easily, since ozone is an electrophilic agent[197] and prefers double to triple bonds (p. 983). Compounds that contain triple bonds generally give carboxylic acids, though sometimes ozone oxidizes them to α-diketones **(19-26).** Aromatic compounds are also attacked less readily than alkenes, but have often been cleaved. Aromatic compounds behave as if the double bonds in the Kekulé structures were really there. Thus benzene gives 3 mol of glyoxal (HCOCHO), and *o*-xylene gives a glyoxal/MeCOCHO/MeCOCOMe ratio of 3:2:1, which shows that in this case cleavage is statistical. With polycyclic aromatic compounds the site of attack depends on the structure of the molecule and on the solvent.[198]



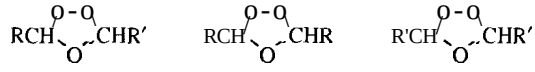
14 **15** 16 17

Although a large amount of work has been done on the mechanism of ozonization (formation of 13), not all the details are known. The basic mechanism was formulated by Criegee.[199] The first step of the Criegee mechanism[200] is a 1,3 dipolar addition **(15-57)** of ozone to the substrate to give the "initial" or "primary" ozonide, the structure of which has been shown to be the 1,2,3-trioxolane (14) by microwave and other spectral methods.[201] However, 14 is highly unstable and cleaves to an aldehyde or ketone (15) and an intermediate,[202] which Criegee showed as a zwitterion (16) but which may be a diradical (17). This compound is usually referred to as a carbonyl oxide.[203] The carbonyl oxide, which we will represent as 16, can then undergo various reactions, three of which lead to normal products. One is a recombination with **15,** the second a dimerization to the bisperoxide (18), and the third a kind of dimerization to 19.[204] If the first path is taken (this is normally possible only if 15 is an aldehyde; most ketones do not do this[205]), hydrolysis of the ozonide gives the normal products. If **18** is formed, hydrolysis of it gives one of the products, and of course 15, which then does not undergo further reaction, is the other. Compound **19,** if formed, can decompose directly, as shown, to give the normal products and

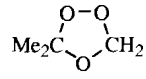


16 Ozonide 16 16

oxygen. In protic solvents, 16 is converted to a hydroperoxide, and these have been isolated, for example, $Me_2C(OOH)-OMe$ from $Me_2C{=}CMe_2$ in methanol. Further evidence for the mechanism is that 18 can be isolated in some cases, (e.g., from $Me_2C{=}CMe_2$). But perhaps the most impressive evidence comes from the detection of cross products. In the Criegee mechanism, the two parts of the original alkene break apart and then recombine to form the ozonide. In the case of an unsymmetrical alkene ($RCH{=}CHR'$), there should be three ozonides:

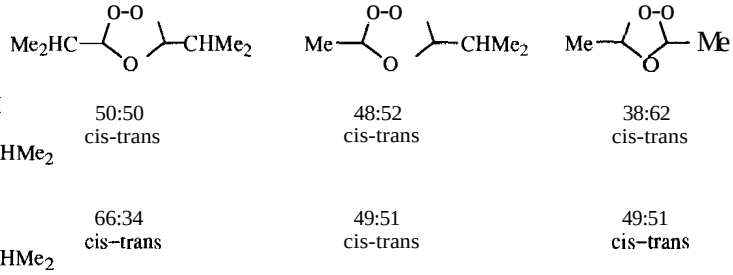


since there are two different aldehydes (15) and two different species of 16, and these can recombine in the three ways shown. Actually *six* ozonides, corresponding to the cis and trans forms of these three, were isolated and characterized for methyl oleate.[206] Similar results have been reported for smaller alkenes, (e.g., 2-pentene, 4-nonene, and even 2-mcthyl-2-pentene).[207] The last-mentioned case is especially interesting, since it is quite plausible that this compound would cleave in only one way, so that only one ozonide (in cis and trans versions) would be found; but this is not so, and three were found for this case too. However, terminal alkenes give little or no cross ozonide formation.[208] In general, the less alkylated end of the alkene tends to go to 15 and the other to 16. Still other evidence[209] for the Criegee mechanism is: (1) When $Me_2C{=}CMe_2$ was ozonized in the presence of HCHO, the



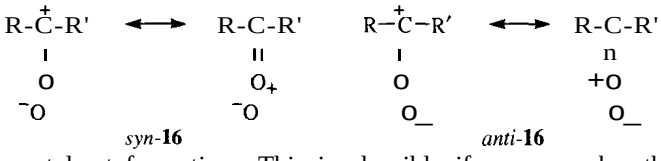
20

ozonide (20) could be isolated;[210] (2) Compound 16 prepared in an entirely different manner (photooxidation of diazo compounds), reacted with aldehydes to give ozonides;[211] and (3) cis and trans alkenes generally give the same ozonide, which would be expected if they cleave first.[212] However, this was not true for $Me_3CCH{=}CHCMe_3$, where the cis alkene gave the cis ozonide (chiefly), and the trans gave the trans.[213] The latter result is not compatible with the Criegee mechanism. Also incompatible with the Criegee mechanism was the finding that the cis/trans ratios of symmetrical (cross) ozonides obtained from *cis*- and *trans*-4-methyl-2-pentene were not the same.[214]



If the Criegee mechanism operated as shown above, the cis/trans ratio for each of the two cross ozonides would have to be identical for the cis and trans alkenes, since in this mechanism they are completely cleaved.

The above stereochemical results have been explained[215] on the basis of the Criegee mechanism with the following refinements: (1) The formation of 14 is stereospecific, as expected from a 1,3 dipolar cycloaddition. (2) Once they are formed, 16 and 15 remain attracted to each other, much like an ion pair. (3) Compound 16 exists in syn and anti forms, which are produced in different amounts and can hold

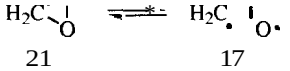


syn-**16** *anti*-**16**

their shapes, at least for a time. This is plausible if we remember that a C=O canonical form contributes to the structure of 16. (4) The combination of 16 and 15 is also a 1,3 dipolar cycloaddition, so configuration is retained in this step too.[216]

Evidence that the basic Criegee mechanism operates even in these cases comes from ^{18}O labeling experiments, making use of the fact, mentioned above, that mixed ozonides (e.g., 20) can be isolated when an external aldehyde is added. Both the normal and modified Criegee mechanisms predict that if ^{18}O-labeled aldehyde is added to the ozonolysis mixture, the label will appear in the ether oxygen (see the reaction between 16 and 15), and this is what is found.[217] There is evidence that the anti-16 couples much more readily than the syn-16.[218]

The ozonolysis of ethylene[219] in the liquid phase (without a solvent) was shown to take place by the Criegee mechanism.[220] This reaction has been used to study the structure of the intermediate 16 or 17. The compound dioxirane (21) was identified in the reaction mixture[221] at low temperatures and is probably in equilibrium with the biradical 17 (R = H). Dioxirane has been produced in solution but it oxidatively cleaves dialkyl ethers (such as Et–O–Et) via a chain radical process, [222] so the choice of solvent is important.



21 17

Ozonolysis in the gas phase is not generally carried out in the laboratory. However, the reaction is important because it takes place in the atmosphere and contributes to air pollution.[223] There is much evidence that the Criegee mechanism operates in the gas phase too, though the products are more complex because of other reactions that also take place.[224]

OS V, 489, 493; VI, 976; VII, 168; IX, 314. Also see OS IV, 554. For the preparation of ozone, see OS III, 673.

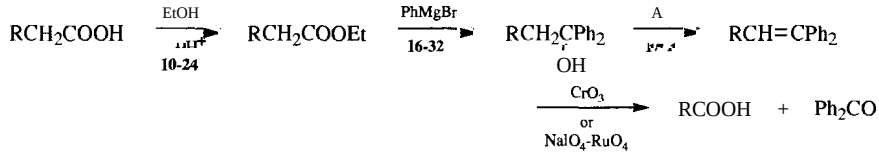
19-10 *Oxidative Cleavage of Double Bonds and Aromatic Rings*

OXO-DE-ALKYLIDENE-BISUBSTITUTION AND SO ON

$$R_2C{=}CHR \xrightarrow{CrO_3} R_2C{=}O + RCOOH$$

Double bonds can be cleaved by many oxidizing agents,[225] the most common of which are neutral or acid permanganate and acid dichromate. The products are generally 2 mol of ketone, 2 mol of carboxylic acid, or 1 mol of each, depending on what groups are attached to the alkene. With ordinary solutions of permanganate or dichromate yields are generally low, and the reaction is seldom a useful synthetic method; but high yields can be obtained by oxidizing with $KMnO_4$ dissolved in benzene containing the crown ether dicyclohexano-18-crown-6 (see p. 105).[226] The crown ether coordinates with K^+, permitting the $KMnO_4$ to dissolve in benzene. A mixture of aqueous $KMnO_4$ and $NaIO_4$ on sand is also effective.[227] Another reagent frequently used for synthetic purposes is the *Lemieux-von Rudloff reagent:* HIO4 containing a trace of MnO_4^-.[228] The MnO_4^- is the actual oxidizing agent, being reduced to the manganate stage, and the purpose of the HIO4 is to reoxidize the manganate back to MnO_4^-. Another reagent that behaves similarly is $NaIO_4$–ruthenium tetroxide.[229]

The *Barbier-Wieland procedure* for decreasing the length of a chain by one carbon involves oxidative cleavage by acid dichromate ($NaIO_4$–ruthenium tetroxide has also been used), but this is cleavage of a 1,1-diphenyl alkene, which generally gives good yields:

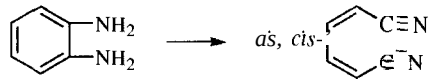


Addition of a catalytic amount of OsO_4 to Jones reagent (19-3) leads to good yields of the carboxylic acid from simple alkenes.[230] With certain reagents, the oxidation of double bonds can be stopped at the aldehyde stage, and in these cases the products are the same as in the ozonolysis procedure. Among these reagents are terf-butyl iodoxybenzene,[231] $KMnO_4$ in $THF–H_2O$,[232] and $NaIO_4–OsO_4$.[233] Electrolysis with $LiClO_4$ in aqueous acetonitrile also cleaves alkenes to give the aldehyde.[234] Enol ethers $RC(OR')=CH_2$ have been cleaved to carboxylic esters $RC(OR')=O$ by atmospheric oxygen.[235]

The mechanism of oxidation probably involves in most cases the initial formation of a glycol (15-35) or cyclic ester,[236] and then further oxidation as in **19-7**.[237] In line with the electrophilic attack on the alkene, triple-bonds are more resistant to oxidation than double bonds. Terminal triple-bond compounds can be cleaved to carboxylic acids ($RC\equiv CH \rightarrow RCOOH$) with thallium(III) nitrate[238] or with [bis(trifluoroacetoxy)iodo]pentafluorobenzene, that is, $C_6F_5I(OCOCF_3)_2$,[239] among other reagents.

Aromatic rings can be cleaved with strong enough oxidizing agents. An important laboratory reagent for this purpose is ruthenium tetroxide along with a co-oxidant such as $NaIO_4$ or NaOCl (household bleach can be used).[240] Examples[241] are the oxidation of naphthalene to phthalic acid[242] and, even more remarkably, of cyclohexylbenzene to cyclohexanecarboxylic acid[243] (note the contrast with 19-11). The latter conversion was also accomplished with ozone.[244] Another reagent that

oxidizes aromatic rings is air catalyzed by V_2O_5. The oxidations of naphthalene to phthalic anhydride and of benzene to maleic anhydride (p. 1021) by this reagent are important industrial procedures.[245] ortho-Diamines have been oxidized with nickel peroxide, with lead tetraacetate,[246] and with O_2 catalyzed by CuCl:[247]



The last-named reagent also cleaves ortho-dihydroxybenzenes (catechols) to give, in the presence of MeOH, the monomethylated dicarboxylic acids[248] HOOC–C=C–C=C–COOMe.

Enamines ($R'_2C{=}NR_2$) are oxidatively cleaved with potassium in sulfuric acid to the ketone ($R'_2C{=}O$).[249]

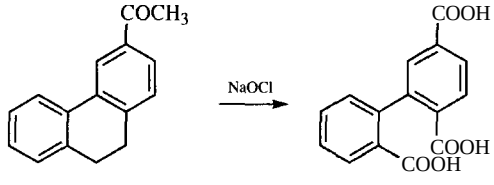
19-11 *Oxidation of Aromatic Side Chains*

OXO,HYDROXY-DE-DIHYDRO,METHYL-TERSUBSTITUTION

$$ArR \xrightarrow{KMnO_4} ArCO_2H$$

Alkyl chains on aromatic rings can be oxidized to COOH groups by many oxidizing agents, including permanganate, nitric acid, and acid dichromate.[250] The method is most often applied to the methyl group, though longer side chains can also be cleaved. However, tertiary alkyl groups are resistant to oxidation, and when they *are* oxidized, ring cleavage usually occurs too.[251] It is usually difficult to oxidize an R group on a fused aromatic system without cleaving the ring or oxidizing it to a quinone **(19-18).** However, this has been done (e.g., 2-methylnaphthalene was converted to 2-naphthoic acid) with aqueous $Na_2Cr_2O_7$.[252] Functional groups can be present anywhere on the side chain and, if in the a position, greatly increase the ease of oxidation. An exception is an a phenyl group. In such cases, the reaction stops at the diaryl ketone stage. Molecules containing aryl groups on different carbons cleave so that each ring gets one carbon atom, for example,



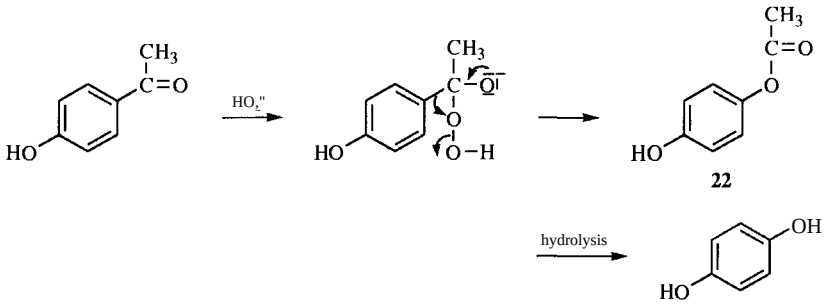
It is possible to oxidize only one alkyl group of a ring that contains more than one. The order of reactivity[253] toward most reagents is $CH_2Ar > CHR_2 > CH_2R > CH_3$.[254] Groups on the ring susceptible to oxidation (OH, NHR, NH_2, etc.) must be

protected. The oxidation can be performed with oxygen, in which case it is autoxidation, and the mechanism is like that in 14-8, with a hydroperoxide intermediate. With this procedure it is possible to isolate ketones from $ArCH_2R$, and this is often done.[255]

The mechanism has been studied for the closely related reaction: $Ar_2CH_2 + CrO_3 \rightarrow Ar_2C{=}O$.[256] A deuterium isotope effect of 6.4 was found, indicating that the rate-determining step is either $Ar_2CH_2 \rightarrow Ar_2CH\cdot$ or $Ar_2CH_2 \rightarrow Ar_2CH^+$. Either way this explains why tertiary groups are not converted to COOH and why the reactivity order is $CHR_2 > CH_2R > CH_3$, as mentioned above. Both free radicals and carbocations exhibit this order of stability (Chapter 5). The two possibilities are examples of categories 2 and 3 (p. 1508). Just how the radical or the cation goes on to the product is not known.

When the alkyl group is one oxidizable to COOH **(19-11),** cupric salts are oxidizing agents, and the OH group is found in a position ortho to that occupied by the alkyl group.[257] This reaction is used industrially to convert toluene to phenol.

In another kind of reaction, an aromatic aldehyde ArCHO or ketone ArCOR' is converted to a phenol ArOH on treatment with alkaline H_2O_2,[258] but there must be an OH or NH_2 group in the ortho or para position. This is called the *Dakin reaction*[59] The mechanism may be similar to that of the Baeyer-Villiger reaction (18-19):[260]



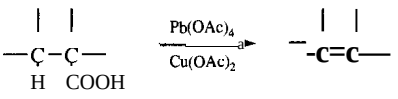
The intermediate **22** has been isolated.[261] The reaction has been performed on aromatic aldehydes with an alkoxy group in the ring, and no OH or NH_2. In this case acidic H_2O_2 was used.[262]

OS I, 159, 385, 392, 543; **II,** 135, 428; **III,** 334, 420, 740, 791, 820, 822; V, 617, 810. Also see OS I, 149; **III,** 759.

19-12 *Oxidative Decarboxylation*

$$RCOOH \xrightarrow{Pb(OAc)_4} ROAc$$

ACETOXY-DE-CARBOXY-SUBSTITUTION



HYDRO-CARBOXYL-ELIMINATION

Carboxylic acids can be decarboxylated[263] with lead tetraacetate to give a variety of products, among them the ester ROAc (formed by replacement of COOH by an acetoxy group), the alkane RH (see 12-38), and, if α, (3 hydrogen is present, the alkene formed by elimination of H and COOH, as well as numerous other products arising from rearrangements, internal cyclizations,[264] and reactions with solvent molecules. When R is tertiary, the chief product is usually the alkene, which is often obtained in good yield. High yields of alkenes can also be obtained when R is primary or secondary, in this case by the use of Cu(OAc)2 along with the $Pb(OAc)_4$.[265] In the absence of $Cu(OAc)_2$, primary acids give mostly alkanes (though yields are generally low) and secondary acids may give carboxylic esters or alkenes. Carboxylic esters have been obtained in good yields from some secondary acids, from β,γ-unsaturated acids, and from acids in which R is a benzylic group. Other oxidizing agents,[266] including Co(III), Ag(II), Mn(III), and Ce(IV), have also been used to effect oxidative decarboxylation.[267]

The mechanism with lead tetraacetate is generally accepted to be of the free-radical type.[268] First, there is an interchange of ester groups:

$$Pb(OAc)_4 + RCOOH \longrightarrow \underset{\textbf{23}}{Pb(OAc)_3OCOR} \quad \text{or} \quad \underset{\textbf{24}}{Pb(OAc)_2(OCOR)_2}$$

There follows a free-radical chain mechanism (shown for 23 and 24 and other lead esters can behave similarly)

Initiation

$$Pb(OAc)_3OCOR \longrightarrow \cdot Pb(OAc)_3 + R\cdot + CO_2$$

(23)

$$R\cdot + Pb(OAc)_3OCOR \longrightarrow R^+ + \cdot Pb(OAc)_2OCOR + OAc^-$$

Propagation

$$\cdot Pb(OAc)_2OCOR \longrightarrow Pb(OAc)_2 + R^- + CO_2$$

Products can then be formed either from $R\cdot$ or R^+. Primary $R\cdot$ abstract H from solvent molecules to give RH. The R^+ group can lose H^+ to give an alkene, react with HOAc to give the carboxylic ester, react with solvent molecules or with another functional group in the same molecule, or rearrange, thus accounting for the large number of possible products. The $R\cdot$ can also dimerize to give RR. The effect of Cu^{2+} ions[269] is to oxidize the radicals to alkenes, thus producing good yields of alkenes from primary and secondary substrates. The Cu^{2+} ion has no effect on tertiary radicals, because these are efficiently oxidized to alkenes by lead tetraacetate.

$$-\overset{|}{\underset{|}{CH-\dot{C}}}- + Cu^{2+} \longrightarrow -\overset{|}{\underset{|}{C=C}}- + H^+ + Cu^+$$

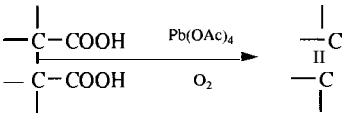
In another type of oxidative decarboxylation, arylacetic acids can be oxidized to aldehydes with one less carbon ($ArCH_2COOH \rightarrow ArCHO$) by tetrabutylammonium periodate.[270] Simple aliphatic carboxylic acids were converted to nitriles with one

less carbon ($RCH_2COOH \rightarrow RC{\equiv}N$) by treatment with trifluoroacetic anhydride and $NaNO_2$ in F_3CCOOH.[271]

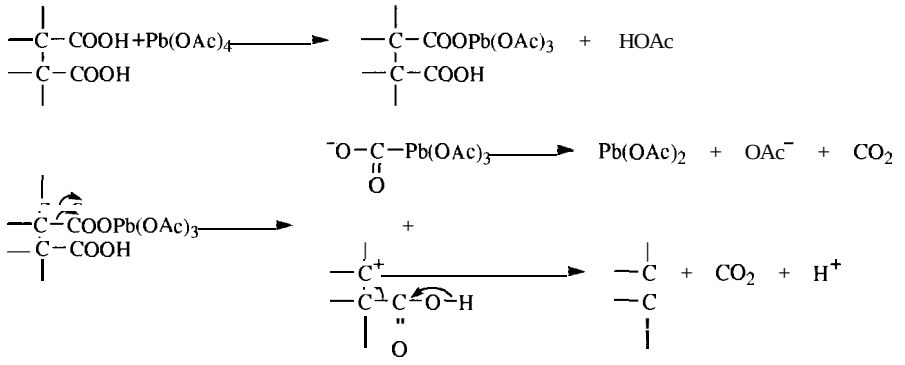
See also 14-37.

19-13 *Bisdecarboxylation*

DICARBOXY-ELIMINATION

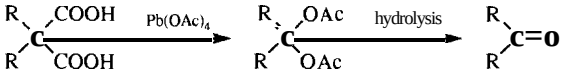


Compounds containing carboxyl groups on adjacent carbons (succinic acid derivatives) can be bisdecarboxylated with lead tetraacetate in the presence of O_2.[263] The reaction is of wide scope. The elimination is stereoselective, but not stereospecific (both *meso-* and *dl-* 2,3-diphenylsuccinic acid gave *trans-* stilbene);[272] a concerted mechanism is thus unlikely. The following mechanism is not inconsistent with the data:



though a free-radical mechanism seems to hold in some cases. Bisdecarboxylation of succinic acid derivatives to give alkenes[273] has also been carried out by other methods, including treatment of the corresponding anhydrides with nickel, iron, or rhodium complexes,[274] by decomposition of the corresponding bis- peroxyesters,[275] and electrolytically.[276]

Compounds containing geminal carboxyl groups (disubstituted malonic acid derivatives) can also be bisdecarboxylated with lead tetraacetate,[277] *gem*-diacetates (acylals) being produced, which are easily hydrolyzable to ketones:[278]



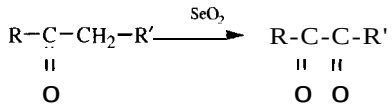
A related reaction involves α-substituted aryl nitriles having a sufficiently acidic a hydrogen, which can be converted to ketones by oxidation with air under phase-transfer conditions.[279] The nitrile is added to NaOH in benzene or Me_2SO containing a catalytic amount of triethylbenzylammonium chloride (TEBA).[280] This

reaction could not be applied to aliphatic nitriles, but an indirect method for achieving this conversion is given in 19-50. α-Dialkylamino nitriles can be converted to ketones, $R_2C(NMe_2)CN \rightarrow R_2C{=}O$, by hydrolysis with $CuSO_4$ in aqueous methanol[281] or by autoxidation in the presence of *t*-BuOK.[282]

C. *Reactions Involving Replacement of Hydrogen by Oxygen*

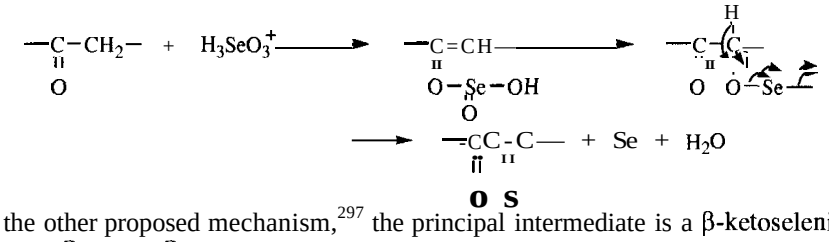
19-14 *Oxidation of Methylene to Carbonyl*

OXO-DE-DIHYDRO-BISUBSTITUTION



Methyl or methylene groups a to a carbonyl can be oxidized with selenium dioxide to give, respectively, α-keto aldehydes and α-diketones.[283] The reaction can also be carried out a to an aromatic ring or to a double bond, though in the latter case, hydroxylation (see 14-4) is the more common result. Although SeO_2 is the reagent most often used, the reaction has also been carried out with N_2O_3 and other oxidizing agents.[284] Substrates most easily oxidized contain two aryl groups on CH_2, and these substrates can be oxidized with many oxidizing agents (see 19-11). Monoaryl alkanes have been oxidized to alkyl aryl ketones with several oxidizing agents, including CrO_3–acetic acid,[285] the Jones reagent,[286] pyridinium chlorochromate,[287] and DDQ,[288] CrO_2Cl_2 with ultrasound,[289] $KMnO_4$ on alumina with microwave irradiation,[290] manganese salen / PhIO (salen= 1,2-bis(salicyledeneamino)ethene (2 —),[291] as well as with SeO_2. Alkenes of the form $C{=}C{-}CH_2$ have been oxidized to α,β-unsaturated ketones[292] by sodium dichromate in HOAc–Ac_2O, by *t*-BuOOH and chromium compounds,[293] as well as electrolytically.[294] Methyl ketones, RCOMe, react with ammonium peroxydisulfate, $(NH_4)_2S_2O_8$, and a catalytic amount of diphenyl diselenide in MeOH to give a-keto acetals, $RCOCH(OMe_2)$.[295]

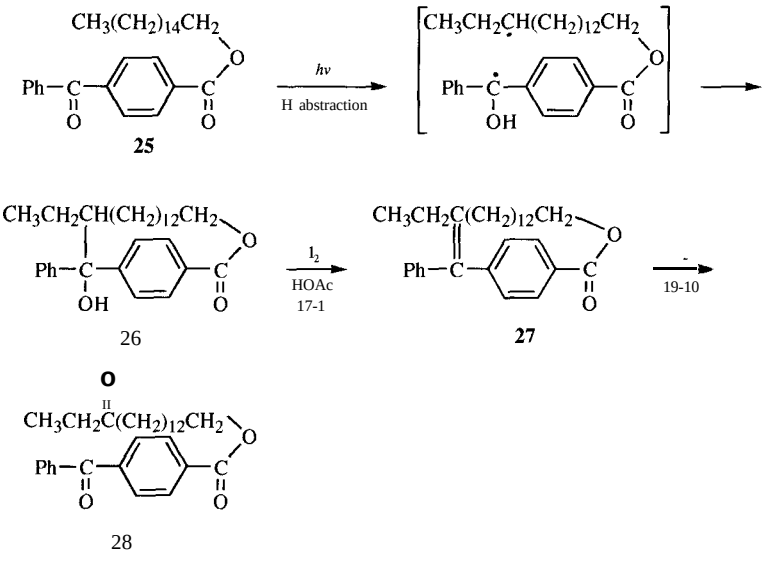
Two mechanisms have been suggested for the reaction with SeO_2. One of these involves a selenate ester of the enol:[296]



In the other proposed mechanism,[297] the principal intermediate is a β-ketoseleninic acid, $-\overset{O}{\overset{\|}{C}}-CH-Se-OH$, and a selenate ester is not involved.

It has proved possible to convert CH_2 to C=O groups, even if they are not near any functional groups, indirectly, by the remote oxidation method of Breslow (see

19-2).[44] In a typical example, the keto ester (25) was irradiated to give the hydroxy lactone (26), which was dehydrated to 27. Ozonolysis of 27 gave the diketo ester



28, in which the C-14 CH_2 group of 25 has been oxidized to a C=O group.[298] The reaction was not completely regioselective: 28 comprised ~60% of the product, with the remainder consisting of other compounds in which the keto group was located at C-12, C-15, and other positions along the carbon chain. Greater regioselectivity was achieved when the aromatic portion was connected to the chain at two positions.[299] In the method so far described, the reaction takes place because one portion of a molecule (the benzophenone moiety) abstracts hydrogen from another portion of the same molecule, that is, the two portions are connected by a series of covalent bonds. However, the reaction can also be carried out where the two reacting centers are actually in different molecules, providing the two molecules are held together by hydrogen bonding. For example, one of the CH_2 groups of hexadecanol monosuccinate, $CH_3(CH_2)_{14}CH_2OCOCH_2CH_2COOH$, was oxidized to a C=O group by applying the above procedure to a mixture of it and benzophenone-4-carboxylic acid *p*-$PhCOC_6H_4COOH$ in CCl_4.[300]

Other remote oxidations[301] have also been reported. Among these are conversion of aryl ketones, $ArCO(CH_2)_3R$, to 1,4-diketones, $ArCO(CH_2)_2COR$, by photoirradiation in the presence of such oxidizing agents as $K_2Cr_2O_7$ or $KMnO_4$,[302] and conversion of alkyl ketones, $RCO(CH_2)_3R'$, to 1,3- and 1,4-diketones with $Na_2S_2O_8$ and $FeSO_4$.[303] 2-Octanol was oxidized to give 2-propyl-5-methyl γ-butyrolactone with lead tetraacetate in a CO atmosphere.[304]

It is possible to perform the conversion $CH_2 \rightarrow C{=}O$ on an alkane, with no functional groups at all, though the most success has been achieved with substrates in which all CH_2 groups are equivalent, such as unsubstituted cycloalkanes. One method uses H_2O_2 and bis(picolinato)iron(II). With this method, cyclohexane was converted with 72% efficiency to give 95% cyclohexanone and 5% cyclohexanol.[305]

This was also accomplished with $BaRu(O)_2(OH)_3$.[306] The same type of conversion, with lower yields (20-30%), has been achieved with the *Gif system*.[307] There are several variations. One consists of pyridine-acetic acid, with H_2O_2 as oxidizing agent and tris(picolinato)iron(III) as catalyst.[308] Other Gif systems use O_2 as oxidizing agent and zinc as a reductant.[309] The selectivity of the Gif systems toward alkyl carbons is $CH_2 > CH \geq CH_3$, which is unusual, and shows that a simple free-radical mechanism (see p. 899) is not involved.[310] Another reagent that can oxidize the CH_2 of an alkane is methyl(trifluoromethyl)dioxirane, but this produces CH—OH more often than C=O (see **14-4**).[311]

OS I, 266; **II,** 509; **III,** 1, 420, 438; IV, 189, 229, 579; VI, 48; IX, 396. Also see OS IV, 23.

19-15 *Oxidation of Methylene to OH, O_2CR, or OR*

HYDROXY (OR ALKOXY) -DE-DIHYDRO-BISUBSTITUTION

$$R-\underset{\underset{0}{\|}}{C}-CH_2-R' \longrightarrow R-\underset{\underset{0}{\|}}{C}-\underset{\underset{OH}{|}}{CH}-R'$$

Methyl or methylene groups α to a carbonyl can be oxidized to give α-hydroxy ketones, aldehydes or carboxylic acid derivatives. The reaction of tetradecanoic acid with the α-oxidase from *Pisum sativum*, in the presence of molecular oxygen, gives 2(*R*)-hydoxytetradecanoic acid with high asymmetric induction.[312] α-Hydroxyketones can be generated from silyl enol ethers with a catalytic amount of $MeReO_3$ and H_2O_2.[313] Methanesulfonic acid and CuO converts ketones to α-mesyloxy (MsO—) ketones[314] and PhI(OH)OTs converts ketones to α-toxyloxy (OTs) ketones.[315] The α′-position of α,β-unsaturated ketones can be selectively oxidized.[316]

Benzylic methylene groups can also be oxidized. Typical reagents include manganese salen and PhIO[317] or peroxides.[318] α-Hydroxy ethers are also generated by reaction of this regents with ethers.[319] Simple alkanes can be converted to esters with dialkyloxiranes. Cyclohexane was converted to cyclohexyl trifiuoroacetate with di(trifluoromethyl) dioxirane and trifluoroacetic anhydride[320] and also with $RuCl_3$/$MeCO_3H$/CF_3CO_2H.[321] Dimethyl dioxirane converts alkanes to alcohols in some cases.

Allylic methylene groups can be converted to ester (—CHOCOR) derivatives in a similar manner using copper triflate.[323] Cupric acetate has also been used[324] as well as Cu_2O.[325] Acyl peroxides have been used as well.[326]

19-16 *Oxidation of Arylmethanes*

OXO-DE-DIHYDRO-BISUBSTITUTION

$$ArCH_3 \xrightarrow{CrO_2Cl_2} ArCHO$$

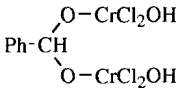
Methyl groups on an aromatic ring can be oxidized to the aldehyde stage by several oxidizing agents. The reaction is a special case of **19-14.** When the reagent is

chromyl chloride (CrO_2Cl_2), the reaction is called the *Étard reaction*[327] and the yields are high.[328] Another oxidizing agent is a mixture of CrO_3 and Ac_2O. In this case, the reaction stops at the aldehyde stage because the initial product is ArCH(OAc)2 (an acylal), which is resistant to further oxidation. Hydrolysis of the acylal gives the aldehyde.

Among other oxidizing agents[329] that have been used to accomplish the conversion of $ArCH_3$ to ArCHO are ceric ammonium nitrate,[330] ceric trifluoroacetate,[331] and silver(II) oxide.[332] Oxidation of $ArCH_3$ to carboxylic acids is considered at **19-11.**

Conversion of $ArCH_3$ to ArCHO can also be achieved indirectly by bromination to give $ArCHBr_2$ (14-1), followed by hydrolysis (10-2).

The mechanism of the Étard reaction is not completely known.[333] An insoluble complex is formed on addition of the reagents, which is hydrolyzed to the aldehyde. The complex is probably a kind of acylal, but what the structure is not fully settled, though many proposals have been made as to its structure and as to how it is



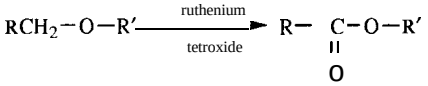
29

hydrolyzed. It is known that $ArCH_2Cl$ is not an intermediate (see **19-19),** since it reacts only very slowly with chromyl chloride. Magnetic susceptibility measurements[334] indicate that the complex from toluene is 29, a structure first proposed by Étard. According to this proposal the reaction stops after only two hydrogens have been replaced because of the insolubility of 29. There is a disagreement on how 29 is formed, assuming that the complex has this structure. Both an ionic[335] and a free-radical[336] process have been proposed. An entirely different structure for the complex was proposed by Nenitzescu and co-workers.[337] On the basis of ESR studies they proposed that the complex is $PhCH_2OCrCl_2OCrOCl_2OH$, which is isomeric with 29. However, this view has been challenged by Wiberg and Eisenthal,[336] who interpret the ESR result as being in accord with 29. Still another proposal is that the complex is composed of benzaldehyde coordinated with reduced chromyl chloride.[338]

OS **II,** 441; **III,** 641; IV, 31,713.

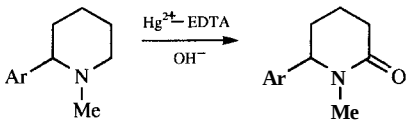
19-17 *Oxidation of Ethers to Carboxylic Esters and Related Reactions*

OXO-DE-DIHYDRO-BISUBSTITUTION



Ethers in which at least one group is primary alkyl can be oxidized to the corresponding carboxylic esters in high yields with ruthenium tetroxide.[339] Molecular oxygen with a binuclear copper (II) complex[340] or $PdCl_2/CuCl_2/CO$[341] also converts ethers to esters. Cyclic ethers give lactones.[342] The reaction, a special case of **19-14,**

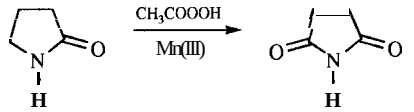
has also been accomplished with CrO_3 in sulfuric acid,[343] and with benzyltriethylammonium permanganate.[344]



30

EDTA = ethylenediaminetetraacetic acid

In a similar reaction, tertiary amines are converted to amides[345] and cyclic tertiary amines (e.g., 30) can be converted to lactams by oxidation with $Hg^{(II)}$–EDTA complex in basic solution.[346] Lactams,

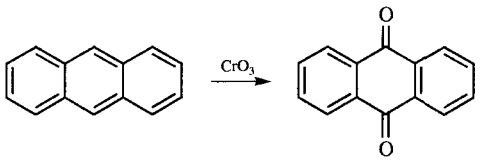


31

which need not be N-substituted (e.g., 31), can be converted to cyclic imides by oxidation with a hydroperoxide or peroxyacid and an Mn(II) or Mn(III) salt.[347]

19-18 *Oxidation of Aromatic Hydrocarbons to Quinones*

ARENE-QUINONE TRANSFORMATION



Condensed aromatic systems (including naphthalenes) can be directly oxidized to quinones by various oxidizing agents.[348] Yields are generally not high, though good yields have been reported with ceric ammonium sulfate.[349] Benzene cannot be so oxidized by strong oxidizing agents but can be electrolytically oxidized to benzoquinone.[350]

OS IV, 698, 757. Also see OS II, 554.

19-19 *Oxidation of Primary Halides and Esters of Primary Alcohols to Aldehydes*[351]

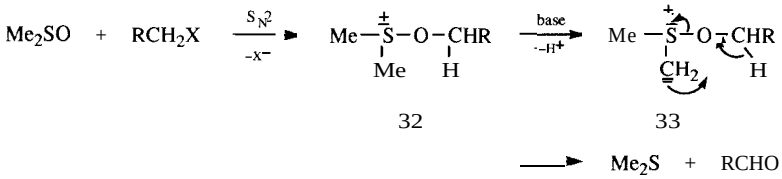
OXO-DE-HYDRO,HALO-BISUBSTITUTION

$$RCH_2Cl \xrightarrow{Me_2SO} RCHO$$

Primary alkyl halides (chlorides, bromides, and iodides) can be oxidized to aldehydes easily and in good yields with DMSO.[352] Tosyl esters of primary alcohols can be similarly converted to aldehydes,[353] and epoxides[354] give α-hydroxy ketones

or aldehydes.[355] The reaction with tosyl esters is an indirect way of oxidizing primary alcohols to aldehydes (19-3).

The mechanism of these DMSO oxidations is probably as follows:[356]



32 33

though in some cases the base abstracts a proton directly from the carbon being oxidized, in which case the ylid 33 is not an intermediate. Alkoxysulfonium salts (32) have been isolated.[357] This mechanism predicts that secondary compounds should be oxidizable to ketones, and this is the case. In a related procedure for the oxidation of alcohols, the intermediate 32[358] is formed without the use of DMSO by treating the substrate with a complex generated from chlorine or NCS and dimethyl sulfide.[359]

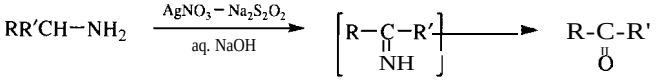
Another way to oxidize primary alkyl halides to aldehydes is by the use of hexamethylenetetramine followed by water. However, this reaction, called the *Sommelet reaction*,[360] is limited to benzylic halides. The reaction is seldom useful when the R in RCH_2Cl is alkyl. The first part of the reaction is conversion to the amine $ArCH_2NH_2$, which can be isolated. Reaction of the amine with excess hexamethylenetetramine gives the aldehyde. It is this last step that is the actual Sommelet reaction, though the entire process can be conducted without isolation of intermediates. Once the amine is formed, it is converted to an imine ($ArCH_2N{=}CH_2$) with formaldehyde liberated from the reagent. The key step then follows: Transfer of hydrogen from another mole of the arylamine to the imine. This last imine is then hydrolyzed by water to the aldehyde. Alternatively, the benzylamine may transfer hydrogen directly to hexamethylenetetramine.

Another reagent that convert benzylic halides to aldehydes is pyridine followed by *p*-nitrosodimethylaniline and then water, called the *Kröhnke reaction.* Primary halides and tosylates have been oxidized to aldehydes by trimethylamine N-oxide,[361] and by pyridine N-oxide with microwave irradiation.[362]

OS II, 336: III, 811; IV, 690, 918, 932; V, 242, 668, 825, 852, 872. Also see OS V, 689; VI, 218.

19-20 *Oxidation of Amines or Nitro Compounds to Aldehydes, Ketones, or Dihalides*

OXO-DE-HYDRO,AMINO-BISUBSTITUTION (OVERALL TRANSFORMATION)



Primary aliphatic amines can be oxidized to aldehydes or ketones.[363] Other reagents used[364] have been *N*-bromoacetamide[365] (for benzylic amines), 3,5-di-*tert*-butyl-1,2-benzoquinone,[366] and aqueous NaOCl with phase-transfer catalysts.[367] Benzylic

amine salts $PhCHRNR'_2H^+Cl^-$ (R,R' =H or alkyl) give benzaldehydes or aryl ketones when heated in Me_2SO.[368] Several indirect methods for achieving the conversion $RR'CHNH_2 \rightarrow RR'C{=}O$ (R' = alkyl, aryl, or H) have been reported.[369]

Primary, secondary, and tertiary aliphatic amines have been cleaved to give aldehydes, ketones, or carboxylic acids with aqueous bromine[370] and with neutral permanganate.[371] The other product of this reaction is the amine with one less alkyl group. In a different type of procedure, primary alkyl primary amines can be converted to *gem*-dihalides, $RCH_2NH_2 \rightarrow RCHX_2$ (X = Br or Cl), by treatment with an alkyl nitrite and the anhydrous copper(I) halide.[372]

Primary and secondary aliphatic nitro compounds have been oxidized to aldehydes and ketones, respectively ($RR'CHNO_2 \rightarrow RR'C{=}O$) with sodium chlorite under phase-transfer conditions,[373] TPAP,[374] Oxone®,[375] as well as with other reagents.[376]

19-21 *Oxidation of Primary Alcohols to Carboxylic Acids or Carboxylic Esters*

OXO-DE-DIHYDRO-BISUBSTITUTION

$$RCH_2OH \xrightarrow{CrO_3} RCOOH$$

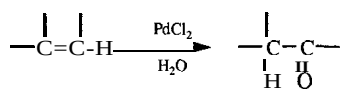
Primary alcohols can be oxidized to carboxylic acids by many strong oxidizing agents including chromic acid, permanganate,[377] and nitric acid.[378] Other reagents include H_5IO_6/CrO_3.[379] The reaction can be looked on as a combination of **19-3** and **14-6.** When acidic conditions are used, a considerable amount of carboxylic ester $RCOOCH_2R$ is often isolated, though this is probably not formed by a combination of the acid with unreacted alcohol, but by a combination of intermediate aldehyde with unreacted alcohol to give an acetal or hemiacetal, which is oxidized to the ester.[380] The $RCOOCH_2R$ compound can be made the main product by treating the alcohol with (1) $Ru_3(CO)_{12}$ and diphenylacetylene, or with a complex formed from these two reagents;[381] (2) Pd salts and CCl_4 in the presence of K_2CO_3;[382] or (3) $RuH_2(PPh_3)_4$.[383] Primary alcohols RCH_2OH can be directly oxidized to acyl fluorides RCOF with cesium fluoroxysulfate.[384] Lactones can be prepared by oxidizing diols in which at least one OH is primary,[385] and addition of a chiral additive such as sparteine leads to lactones with high asymmetric induction.[386]

Primary alkyl ethers can be selectively cleaved to carboxylic acids by aqueous Br_2 ($RCH_2OR' \rightarrow RCOOH$).[387] Aldehydes RCHO can be directly converted to carboxylic esters RCOOR' by treatment with Br_2 in the presence of an alcohol.[388]

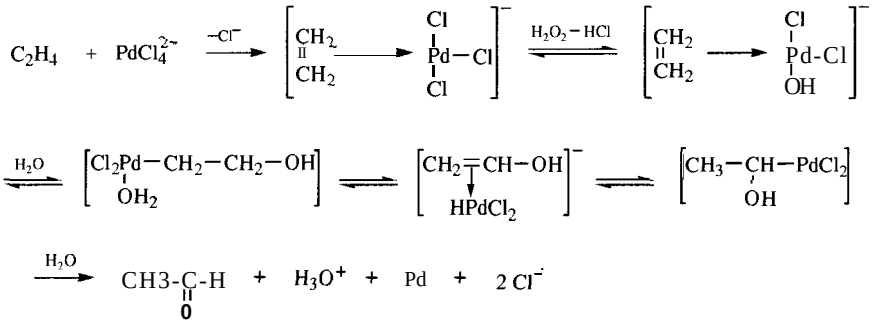
OS I, 138, 168; **IV,** 499, 677; V, 580; **VII,** 406; IX, 462. Also see OS **III,** 745.

19-22 *Oxidation of Alkenes to Aldehydes and Ketones*

1/OXO-(1,2/HYDRO)-*MIGRO*-ATTACHMENT



Monosubstituted and 1,2-disubstituted alkenes can be oxidized to aldehydes and ketones by palladium chloride and similar salts of noble metals.[389] 1,1-Disubstituted alkenes generally give poor results. The reaction is used industrially to prepare acetaldehyde from ethylene (the *Wacker process),* but it is also suitable for laboratory preparations. The palladium chloride is reduced to palladium. Because the reagent is expensive, the reaction is usually carried out with a co-oxidant, most often $CuCl_2$, whose function is to reoxidize the Pd to Pd(II). The $CuCl_2$ is reduced to Cu(I), which itself is reoxidized to Cu(II) by air, so that atmospheric oxygen is the only oxidizing agent actually used up. Many other co-oxidants have been tried, among them O_3, Fe^{3+}, and PbO_2. /er/-Butylhydroperoxide in bromoperfluorooctane/benzene oxidizes styrene to acetophenone is a Wacker-type process.[390] The principal product is an aldehyde only from ethylene: With other alkenes Markovnikov's rule is followed, and ketones are formed predominantly. The generally accepted mechanism involves *n* complexes of palladium.[391]



This mechanism accounts for the fact, established by deuterium labeling, that the four hydrogens of the acetaldehyde all come from the original ethylene and none from the solvent.

Similar reactions have been carried out with other oxidizing agents. An example involving migration of an alkyl group instead of hydrogen is oxidation of $Me_2C{=}CMe_2$ with peroxytrifluoroacetic acid-boron trifluoride to give Me_3COMe (pinacolone).[392] This reaction consists of epoxidation (15-48) followed by pinacol rearrangement of the epoxide (18-2). A migration is also involved in the conversion of $ArCH{=}CHCH_3$ to $ArCH(CH_3)CHO$ by treatment with $I_2{-}Ag_2O$ in aqueous dioxane.[393]

Other reagents used include $Pb(OAc)_4{-}F_3CCOOH$[394] (e.g., $PhCH{=}CH_2 \rightarrow PhCH_2CHO$), H_2O_2 and a Pd catalyst,[395] $H_2O{-}PdCl_2$—polyethylene glycol,[396] $CrO_3{-}H_2SO_4{-}Hg(II)$ salts,[397] and $Hg(OAc)_2$ followed by $PdCl_2$.[398] The reaction has also been accomplished electrochemically.[399]

Alkenes have also been converted to more highly oxidized products. Examples are (1) Treatment with $KMnO_4$ in aqueous acetone containing acetic acid gives α-hydroxy ketones.[400] (2) 1,2-Disubstituted and trisubstituted alkenes give α-chloro ketones when oxidized with chromyl chloride in acetone: RCH=CR'R"—* RCOCClR'R".[401] (3) α-Iodo ketones can be prepared by treating alkenes with

bis(*s*-collidine)iodine(I) tetrafluoroborate.[402] (4) The $KMnO_4$ in acetic anhydride oxidizes large-ring cycloalkenes to 1,2-diketones.[403]

Enol ethers are oxidized to carboxylic esters ($RCH{=}CHOR' \rightarrow RCH_2COOR'$) with pyridinium chlorochromate[404] and enamines to α-amino ketones ($R^1CH{=}CR_2NR \rightarrow R^1COCR_2NR$) with N-sulfonyloxaziridines.[405] Enamines $R^1R^4C{=}CR^2NR_2^3$ ($R^4 \neq H$) do not give these products, but lose the amino group to give α-hydroxy ketones, $R^1R^4C(OH)COR^2$.[405] Carboxylic acids can be prepared from terminal alkynes ($RC{\equiv}CH \rightarrow RCH_2COOH$) by conversion of the alkyne to its phenylthio ether ($RC{\equiv}CSPh$) and treatment of this with $HgSO_4$ in $HOAc{-}H_2SO_4$.[406]

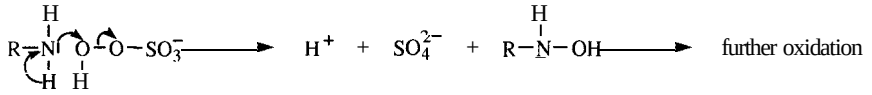
OS VI, 1028; VII, 137; VIII, 208.

19-23 *Oxidation of Amines to Nitroso Compounds and Hydroxylamines*

N-OXO-DE-DIHYDRO-BISUBSTITUTION

$$ArNH_2 \xrightarrow{H_2SO_5} Ar{-}N{=}O$$

Primary aromatic amines can be oxidized[407] to nitroso compounds. Most often the conversion is accomplished by Caro's acid (H_2SO_5) or with H_2O_2 in HOAc.[408] Hydroxylamines, which are probably intermediates in most cases, can sometimes be isolated, but under the reaction conditions are generally oxidized to the nitroso compounds. Primary aliphatic amines can be oxidized in this manner, but the nitroso compound is stable only if there is no α hydrogen. If there is an α hydrogen, the compound tautomerizes to the oxime.[409] Among the reagents used for this oxidation are sodium perborate[410] and $Na_2WO_4{-}H_2O_2$.[411] The mechanism with H_2SO_5 has been postulated to be an example of category 5 (p. 1509).[412]



Secondary amines (R_2NH) are oxidized to hydroxylamines (R_2NHOH), which are resistant to further oxidation, by dimethyldioxirane[413] and by benzoyl peroxide and Na_2HPO_4.[414]

OS III, 334; VIII, 93.

19-24 *Oxidation of Primary Amines, Oximes, Azides, Isocyanates, or Nitroso Compounds to Nitro Compounds*

$$R_3CNH_2 \xrightarrow{KMnO_4} R_3CNO_2$$

$$R_2C{=}NOH \xrightarrow{F_3CCOOOH} R_2CHNO_2$$

Tertiary alkyl primary amines can be oxidized to nitro compounds in excellent yields with $KMnO_4$.[415] This type of nitro compound is not easily prepared in other ways.

All classes of primary amine (including primary, secondary, and tertiary alkyl as well as aryl) are oxidized to nitro compounds in high yields with dimethyl dioxirane.[416] Other reagents that oxidize various types of primary amines to nitro compounds are dry ozone,[417] various peroxyacids,[418] $MeReO_3/H_2O_2$,[419] Oxone®,[420] *tert*-butyl hydroperoxide in the presence of certain molybdenum and vanadium compounds,[421] and sodium perborate.[422]

Dimethyl dioxirane in wet acetone oxidizes isocyanates to nitro compounds ($RNCO \rightarrow RNO_2$).[423] Oximes can be oxidized to nitro compounds with peroxytrifluoroacetic acid, or Oxone®,[424] sodium perborate,[425] among other ways.[415] Primary and secondary alkyl azides have been converted to nitro compounds by treatment with Ph_3P followed by ozone.[426] Aromatic nitroso compounds are easily oxidized to nitro compounds by many oxidizing agents.[427]

OS **III,** 334; V, 367, 845; VI, 803.

19-25 *Oxidation of Thiols and Other Sulfur Compounds to Sulfonic Acids*

THIOL-SULFONIC ACID OXIDATION

$$RSH \xrightarrow{HNO_3} RSO3H$$

Thiols, sulfoxides, sulfones, disulfides,[428] and other sulfur compounds can be oxidized to sulfonic acids with many oxidizing agents, though for synthetic purposes the reaction is most important for thiols.[429] Among oxidizing agents used are boiling nitric acid, barium permanganate, and dimethyl dioxirane.[430] Autoxidation (oxidation by atmospheric oxygen) can be accomplished in basic solution.[431] Oxidation of thiols with chlorine and water gives sulfonyl chlorides directly.[432] Thiols can also be oxidized to disulfides **(19-32).**

OS **II,** 471; **III,** 226. Also see OS V, 1070.

D. *Reactions in Which Oxygen Is Added to the Substrate*

19-26 *The Oxidation of Alkynes to α-Diketones*

DIOXO-BIADDITION

$$R-C\equiv C-R' \xrightarrow[\text{tetroxide}]{\text{ruthenium}} R-\underset{\underset{O}{\|}}{C}-\underset{\underset{O}{\|}}{C}-R'$$

Internal alkynes have been oxidized[433] to α-diketones by several oxidizing agents,[434] including neutral $KMnO_4$,[435] bis(trifluoroacetoxy)iodobenzene,[436] $NaIO_4$–RuO_2,[437] I_2–Me_2SO,[438] $MeReO_3/H_2O_2$,[439] as well as by electrooxidation.[440] Ozone generally oxidizes triple-bond compounds to carboxylic acids (19-9), but ot-diketones are sometimes obtained instead. The SeO_2 compound with a small amount of H_2SO_4 oxidizes alkynes to ot-diketones as well as arylacetylenes to ot-keto acids ($ArC\equiv CH \rightarrow ArCOCOOH$).[441]

19-27 *Oxidation of Tertiary Amines to Amine Oxides*

N-OXYGEN-ATTACHMENT

$$R_3N \xrightarrow{H_2O_2} R_3\overset{+}{N}-\overset{-}{O}$$

Tertiary amines can be converted to amine oxides by oxidation. Hydrogen peroxide is often used, but peroxyacids are also important reagents for this purpose. Pyridine and its derivatives are oxidized only by peroxyacids.[442] In the attack by hydrogen peroxide there is first formed a trialkylammonium peroxide, a hydrogen-bonded complex represented as $R_3N{\cdot}H_2O_2$, which can be isolated.[443] The decomposition of this complex probably involves an attack by the OH^+ moiety of the H_2O_2. Oxidation with Caro's acid has been shown to proceed in this manner:[444]

$$R_3N \longrightarrow \underset{H}{O}-O-SO_3H \longrightarrow HSO_4^- + R_3\overset{+}{N}-OH \xrightarrow{-H^+} R_3\overset{+}{N}-O^-$$

This mechanism is the same as that of **19-23;** the products differ only because tertiary amine oxides cannot be further oxidized. The mechanism with other peroxyacids is probably the same. Racemic β-hydroxy tertiary amines have been resolved by oxidizing them with *t*-BuOOH and a chiral catalyst one enantiomer reacts faster than the other.[445] This kinetic resolution gives products with enantiomeric excesses of > 90%.

It is noted that azo compounds can be oxidized to azoxy compounds by peroxyacids[446] or by hydroperoxides and molybdenum complexes.[447]

OS **IV,** 612, 704, 828; **VI,** 342, 501; **VIII,** 87.

19-28 *Oxidation of Thioethers to Sulfoxides and Sulfones*

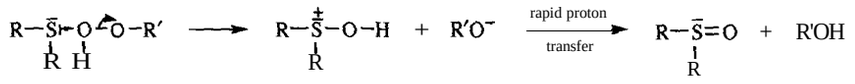
S-OXYGEN-ATTACHMENT

$$R-\overset{-}{S}-R \xrightarrow{H_2O_2} R-\overset{-}{\underset{\underset{O}{\|}}{S}}-R \xrightarrow{KMnO_4} R-\overset{O}{\underset{O}{\overset{\|}{\underset{\|}{S}}}}-R$$

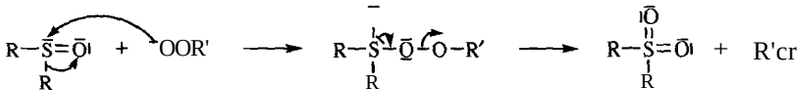
Thioethers can be oxidized to sulfoxides by 1 mol of 30% H_2O_2 or by many other oxidizing agents,[448] including $NaIO_4$,[449] dioxiranes,[450] $MeReO_3/H_2O_2$,[450] O_2 and a ceric ammonium nitrate catalyst,[452] sodium perborate,[422] and peroxyacids.[453] Sulfoxides can be further oxidized to sulfones by another mole of H_2O_2, $KMnO_4$, sodium perborate, or a number of other agents. If enough oxidizing agent is present, thioethers can be directly converted to sulfones without isolation of the sulfoxides.[454] These reactions give high yields, and many functional groups do not interfere.[455] As with tertiary amines **(19-27),** racemic thioethers can be kinetically resolved by oxidation to sulfoxides with an optically active reagent, and this has often been done.[456] In addition, the use of chiral additives in conjunction with various oxidizing agents leads to chiral nonracemic sulfoxide with good-to-excellent asymmetric induction.[457] Chiral sulfur reagents are also known.[458]

Selenides (R_2Se) can be oxidized to selenoxides and selenones.[459] It is possible to oxidize a thioether to a sulfoxide in the presence of an alcohol moiety using MnO_2/HCl.[460]

When the oxidizing agent is a peroxide, the mechanism[461] of oxidation to the sulfoxide is similar to that of 19-27.[462]



The second oxidation, which is normally slower than the first[463] (which is why sulfoxides are so easily isolable), has the same mechanism in neutral or acid solution, but in basic solution it has been shown that the conjugate base of the peroxy compound ($R'OO^-$) also attacks the SO group as a nucleophile:[464]

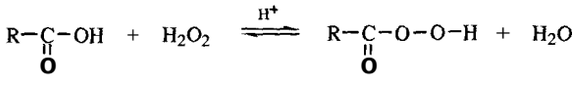


Thioethers can be oxidized directly to the sulfone by treatment with excess NaOCl[465] tetramethylperruthenate (TPAP,)[466] or with $NaIO_4$/catalytic $RuCl_3$.[467]

OS V, 791; VI, 403, 404, 482; VII, 453, 491; VIII, 464, 543; IX, 63. Also see OS V, 723; VI, 23.

19-29 *Oxidation of Carboxylic Acids to Peroxy Acids*

PEROXY-DE-HYDROXY-SUBSTITUTION

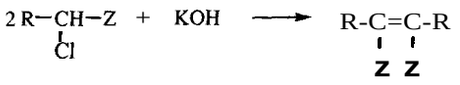


The oxidation of carboxylic acids with H_2O_2 and an acid catalyst is the best general method for the preparation of peroxy acids.[468] A mixture of $Me_2C(OMe)OOH$ and DCC has also been used.[469] The most common catalyst for aliphatic R is concentrated sulfuric acid. The reaction is an equilibrium and is driven to the right by removal of water or by the use of excess reagents. For aromatic R the best catalyst is methanesulfonic acid, which is also used as the solvent.

E. ***Oxidative*** *Coupling*

19-30 *Coupling Involving Carbanions*

DE-HYDRO,CHLORO-COUPLING



Alkyl halides with an electron-withdrawing group on the halogen-bearing carbon can be dimerized to alkenes by treatment with bases. The Z group may be nitro, aryl,

and so on. It is likely that in most cases the mechanism[470] involves nucleophilic substitution followed by elimination[471] (illustrated for benzyl chloride):

$$PhCH_2Cl \xrightarrow{base} PhCHCl^- \xrightarrow[S_N]{PhCH_2Cl} PhCHClCH_2Ph \xrightarrow{-HCl} PhCH{=}CHPh$$

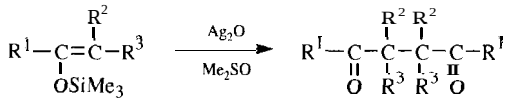
α,α-Dibromotoluenes ($ArCHBr_2$) give tolanes ($ArC{\equiv}CAr$), by debromination of the intermediates $ArCBr{=}CBrAr$.[472] In a related reaction, diarylmethane dihalides (AR_2CX_2) have been dimerized to tetraaryl alkenes ($Ar_2C{=}CAr_2$) with copper,[473] and with iron(II) oxalate dihydrate.[474]

A somewhat different type of coupling is observed when salts of P-keto esters, arylacetonitriles ($ArCH_2CN$), and other compounds of the form ZCH_2Z' are treated with an oxidizing agent such as iodine,[475] or Cu(II) salts.[476] Arylmethanesulfonyl chlorides ($ArCH_2SO_2Cl$) couple to give $ArCH{=}CHAr$ when treated with Et_3N.[477]

OS **II,** 273; **IV,** 372, 869, 914; **VIII,** 298. Also see OS I, 46; **IV,** 877.

19-31 *Dimerization of Silyl Enol Ethers or of Lithium Enolates*

3/*O*-DE-TRIMETHYLSILYL-1/*C*-COUPLING



34

Silyl enol ethers can be dimerized to symmetrical 1,4-diketones by treatment with Ag_2O in DMSO or certain other polar aprotic solvents.[478] The reaction has been performed with R^2, R^3 = hydrogen or alkyl, though best yields are obtained when $R^2 = R^3 = H$. In certain cases, unsymmetrical 1,4-diketones have been prepared by using a mixture of two silyl enol ethers. Other reagents that have been used to achieve either symmetrical or cross-coupled products are iodosobenzene–BF_3–Et_2O,[479] ceric ammonium nitrate,[480] and lead tetraacetate.[481] If $R^1 = OR$ (in which case the substrate is a ketene silyl acetal), dimerization with $TiCl_4$ leads to a dialkyl succinate (34, $R^1 = OR$).[482]

In a similar reaction, lithium enolates, $RC(OLi){=}CH_2$, were dimerized to 1,4-diketones, $RCOCH_2CH_2COR$, with $CuCl_2$, $FeCl_3$, or copper(II) triflate, in a nonprotic solvent.[483]

OS **VIII,** 467.

19-32 *Oxidation of Thiols to Disulfides*

S-DE-HYDROGEN-COUPLING

$$2\ RSH \xrightarrow{H_2O_2} RSSR$$

Thiols are easily oxidized to disulfides.[484] Hydrogen peroxide is the most common reagent,[485] but many oxidizing agents give the reaction, among them KMnO

$CuSO_4$,[486] Me_2SO–I_2,[487] Br_2 under phase-transfer conditions,[488] sodium perborate,[489] and NO. It can also be done electrochemically.[490] However, strong oxidizing agents may give **19-26.** Even the oxygen in the air oxidizes thiols on standing, if a small amount of base is present. The reaction is reversible (see **19-54),** and the interconversion between cysteine and cystine is an important one in biochemistry.

The mechanism has been studied for several oxidizing agents and varies with the agent.[491] For oxygen it is[492]

$$\begin{aligned}
&RSH + B^- \rightleftharpoons RS^- + BH\\
&RS^- + O_2 \longrightarrow RS\text{-} + \cdot O_2^-\\
&RS^- + \cdot O_2^- \longrightarrow RS\cdot + O_2^{2-}\\
&2\,O_2^{2-} + 2\,BH \longrightarrow 2\,OH'' + 2\,B^- + O_2
\end{aligned}$$

With respect to the sulfur, this mechanism is similar to that of **14-16,** involving as it does loss of a proton, oxidation to a free radical, and radical coupling.

Unsymmetrical disulfides can be prepared[493] by treatment of a thiol RSH with diethyl azodicarboxylate (EtOOCN=NCOOEt) to give an adduct, to which another thiol R'SH is then added, producing the disulfide RSSR'.[494]

OS **III,** 86, 116.

Reductions: Selectivity[495]

It is often necessary to reduce one group in a molecule without affecting another reducible group. It is usually possible to find a reducing agent that will do this. The most common broad-spectrum reducing agents are the metal hydrides[496] and hydrogen (with a catalyst).[497] Many different metal-hydride systems and hydrogenation catalysts have been investigated in order to find conditions under which a given group will be reduced chemoselectively. Tables 19.2,[498] 19.3,[498] and 19.4[498] list the reactivity of various functional groups toward catalytic hydrogenation. $LiAlH_4$, and BH_3, respectively. Table 19.5[499] shows which groups can be reduced by catalytic hydrogenation and various metal hydrides. Of course, the tables cannot be exact, because the nature of R and the reaction conditions obviously affect reactivity. Nevertheless, the tables do give a fairly good indication of which reagents reduce which groups.[500] Lithium aluminium hydride is very powerful and unselective reagent.[501] Consequently, other metal hydrides are generally used when chemoselectivity is required. As mentioned on page 1199, a number of less reactive (and more selective) reagents have been prepared by replacing some of the hydrogens of $LiAlH_4$ with alkoxy groups (by treatment of $LiAlH_4$ with ROH).[502] Most of the metal hydrides are nucleophilic reagents and attack the carbon atom of a carbon–hetero single or multiple bond. However, BH_3[503,504] and AlH_3[505] are electrophiles (Lewis acids) and attack the hetero atom. This accounts for the different patterns of selectivity shown in the tables.

The reactions in this section are grouped into classifications based on bond changes, similar to those used for the oxidation reactions. These sections are (A) reactions involving replacement of oxygen by hydrogen, (B) reactions in which

TABLE 19.2 The Ease of Reduction of Various Functional Groups [a] Toward Catalytic Hydrogenation*

Reaction	Substrate	Product	
10-89	$RCOCl$	RCHO	Easiest
19-41	RNO_2	RNH_2

oxygen is removed from the substrate, (C) reduction with cleavage, and (D) reductive coupling.

A. *Reactions Involving Replacement of Oxygen by Hydrogen*

In reactions **19-33-19-37,** a C=O group is reduced to a CH_2 group.

19-33 *Reduction of Carbonyl to Methylene in Aldehydes and Ketones*

DIHYDRO-DE-OXO-BISUBSTITUTION

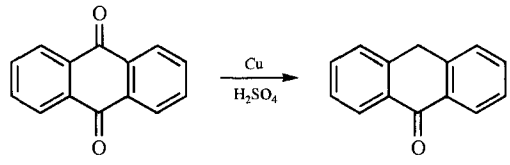
$$R-\underset{\underset{O}{\|}}{C}-R' \xrightarrow[HCl]{Zn-Hg} R-CH_2-R'$$

There are various ways of reducing the C=O group of aldehydes and ketones to CH_2.[512] The two oldest, but still very popular, methods are the *Clemmensen reduction*[513] and the *Wolff–Kishnerreduction.* The Clemmensen reduction consists of heating the aldehyde or ketone with zinc amalgam and aqueous HCl.[514] Ketones are reduced more often than aldehydes. In the Wolff–Kishner reduction,[515] the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH or KOH). The *Huang-Minion modification*[516] of the Wolff-Kishner reaction, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. The reaction can also be carried out under more moderate conditions (room temperature) in DMSO with potassium tert-butoxide as base.[517] The Wolff-Kishner reaction can also be applied to the semicarbazones of aldehydes or ketones. The Clemmensen reduction is usually easier to perform, but it fails for acid-sensitive and high molecular weight substrates. For these cases, the Wolff-Kishner reduction is quite useful. For high molecular weight substrates, a modified Clemmensen reduction, using activated zinc and gaseous HC1 in an organic solvent such as ether or acetic anhydride, has proved successful.[518] The Clemmensen and Wolff-Kishner reactions are complementary, since the former uses acidic and the latter basic conditions.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under Clemmensen conditions,[519] 7-hydroxy ketones give either ketones (hydrogenolysis of the OH, **10-81)** or alkenes, and 1,3-diones usually undergo rearrangement, (e.g., $MeCOCH_2COMe \rightarrow MeCOCHMe_2$.[520] Neither method is suitable for α,β-unsaturated ketones. These give pyrazolines[521] under Wolff-Kishner conditions, while under Clemmensen conditions both groups of these molecules may be reduced or if only one group is reduced, it is the C=C bond.[522] Sterically hindered ketones are resistant to both the Clemmensen and Huang-Minion procedures but can be reduced by vigorous treatment with anhydrous hydrazine.[523] In the Clemmensen reduction, pinacols **(19-55)** are often side products.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH_2.[524] Among these are Me_3SiCl followed by $Et_3SiH/TiCl_4$,[525] $Ni(OAc)_2$ on

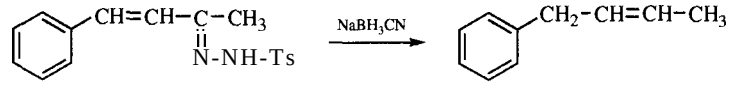
borohydride exchange resin,[526] Et_3SiH on pyridinium poly(hydrogen fluoride) [abbreveated as PPHF],[527] and, for aryl ketones (ArCOR and ArCOAr), $NaBH_4$–F_3CCOOH,[528] $NaBH_4$–$AlCl_3$,[529] $HCOONH_4$–Pd–C,[530] or trialkylsilanes in F_3CCOOH.[531] Most of these reagents also reduce aryl aldehydes ArCHO to methylbenzenes $ArCH_3$.[532] Aliphatic aldehydes RCHO can be reduced to RCH_3 with titanocene dichloride, $(C_5H_5)_2TiCl_2$.[533] One carbonyl group of 1,2-diketones can be selectively reduced by H_2S with an amine catalyst[534] or by HI in refluxing acetic acid.[535] One carbonyl group of quinones can be reduced with copper and sulfuric acid or with tin and HC1:[536]



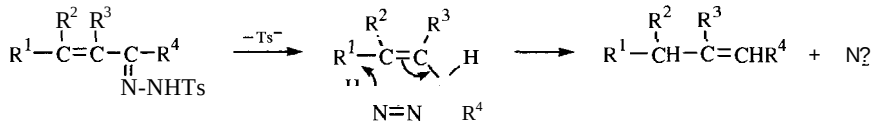
One carbonyl group of 1,3-diketones was selectively reduced by catalytic hydrogenolysis.[537]

The carbonyl of acid derivatives can be reduced in some cases. Lactones are converted to cyclic ethers by treatment with Cp_2TiCl_2 followed by Et_3SiH on Amberlyst 15®.[538]

An indirect method of accomplishing the reaction is reduction of tosylhydrazones ($R_2C{=}N{-}NHTs$) to R_2CH_2 with $NaBH_4$, BH_3, catecholborane, bis(benzyloxy)-borane, or $NaBH_3CN$. The reduction of α,β-unsaturated tosylhydrazones with $NaBH_3CN$, with $NaBH_4$–HOAc, or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring,[539] for example,



A cyclic mechanism is apparently involved:



Another indirect method is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization of this (14-34).

It is interesting to see that amines can be deaminated to give the corresponding methylene compounds with low-valent titanium ($TiCl_3$/Li/THF).[540]

The first step in the mechanism[541] of the Wolff–Kishner reaction consists of formation of the hydrazone (16-19).

$$R_2C{=}O \longrightarrow R_2C{=}N{-}NH_2$$

It is this species that undergoes reduction in the presence of base, most likely in the following manner:

$$R_2C{=}H{-}NH_2 \overset{OH^-}{\rightleftharpoons} R_2CH{-}N{=}NH + OH^- \longrightarrow R_2CH{-}N{=}N^- + H_2O$$

$$R_2CH{-}N{=}N^- \xrightarrow{-N_2} R_2\dot{C}H \xrightarrow{H_2O} R_2CH_2 + OH^-$$

Not much is known about the mechanism of the Clemmensen reduction. Several mechanisms have been proposed,[542] including one going through a zinc-carbene intermediate.[543] One thing reasonably certain is that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the Wolff–Kishner reduction either.

19-34 *Reduction of Carboxylic Acids to Alcohols*

DIHYDRO-DE-OXO-BISUBSTITUTION

$$RCOOH \xrightarrow{LiAlH_4} RCH_2OH$$

Carboxylic acids are easily reduced to primary alcohols by $LiAlH_4$.[544] The reaction does not stop at the aldehyde stage (but see **10-90).** The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used,[545] but not $NaBH_4$ (see Table 19.5).[546] Catalytic hydrogenation is also generally ineffective.[547] Borane is particularly good for carboxyl groups (Table 19.4) and permits selective reduction of them in the presence of many other groups (though the reaction with double bonds takes place at about the same rate).[548] Borane also reduces carboxylic acid salts.[549] Aluminum hydride reduces COOH groups without affecting carbon-halogen bonds in the same molecule. The reduction has also been carried out with SmI_2 in basic media[550] or aqueous H_3PO_4,[551] or simply with SmI_2 in water.[552] A mixture of $NaBH_4$ and I_2 has been used to reduced amino acids to amino alcohols.[553]

OS **III,** 60; **VII,** 221; 530; **VIII,** 26, 434, 528.

19-35 *Reduction of Amides to Amines*

DIHYDRO-DEOXO-BISUBSTITUTION

$$RCONH_2 \xrightarrow{LiAlH_4} RCH_2NH_2$$

Amides can be reduced[554] to amines with $LiAlH_4$ or by catalytic hydrogenation, though high temperatures and pressures are usually required for the latter. Even with $LiAlH_4$ the reaction is more difficult than the reduction of most other functional groups, and other groups often can be reduced without disturbing an amide function. $NaBH_4$ by itself does not reduce amides, though it does so in the presence of certain other reagents[555] including iodine.[556] Substituted amides can be similarly reduced:

$$RCONHR' \longrightarrow RCH_2NHR'$$

$$RCONR'_2 \longrightarrow RCH_2NR'_2$$

Borane[557] and sodium in 1-propanol[558] are good reducing agents for all three types of amides. Another reagent that reduces disubstituted amides to amines is trichlorosilane.[559] Sodium(dimethylamino)borohydride reduces unsubstituted and disubstituted, but not monosubstituted amides.[560]

With some RCONR , $LiAlH_4$ causes cleavage, and the aldehyde **(10-91)** or alcohol is obtained. Lithium triethylborohydride produces the alcohol with most N,N-disubstituted amides, though not with unsubstituted or N-substituted amides.[561] Lactams are reduced to cyclic amines in high yields with $LiAlH_4$, though cleavage sometimes occurs here too. A mixture of $LiBHEt_3/Et_3SiH$ is also effective.[562] Imides are generally reduced on both sides, though it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, though with acyclic imides cleavage is often obtained, for example,[563]

$$PhN(COMe)_2 \longrightarrow PhNHEt$$

Acyl sulfonamides have been reduced ($RCONHSO_2Ph \rightarrow RCH_2NHSO_2Ph$) with $BH_3{-}SMe_2$[564] and with SmI_2/DMPU,[565]

OS IV, 339, 354, 564; VI, 382; **VII,** 41.

19-36 *Reduction of Carboxylic Esters to Ethers*

DIHYDRO-DE-OXO-BISUBSTITUTION

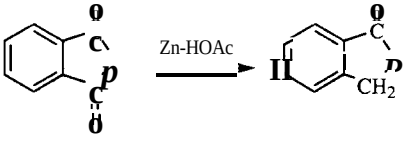
$$RCOOR' \xrightarrow[LiAlH_4]{BF_3\text{-etherate}} RCH_2OR'$$

Carboxylic esters and lactones have been reduced to ethers, though 2 mol of alcohol are more commonly obtained **(19-38).** Reduction to ethers has been accomplished with a reagent prepared from BF_3–etherate and either $LiAlH_4$, $LiBH_4$, or $NaBH_4$,[566] with trichlorosilane and UV light,[567] and with catalytic hydrogenation. The reaction with the BF_3 reagent apparently succeeds with secondary R', but not with primary R', which give **19-38.** Lactones give cyclic ethers.[568] Thiono esters (RCSOR') can be reduced to ethers RCH_2OR' with Raney nickel (**14-34**).[569] Since the thiono esters can be prepared from carboxylic esters **(16-10),** this provides an indirect method for the conversion of carboxylic esters to ethers. Thiol esters RCOSR' have been reduced to thioethers RCH_2SR'.[570]

See also **19-39, 10-86.**

19-37 *Reduction of Cyclic Anhydrides to Lactones and Acid Derivatives to Alcohols*

DIHYDRO-DE-OXO-BISUBSTITUTION



Cyclic anhydrides can give lactones if reduced with Zn–HOAc, with hydrogen and platinum or $RuCl_2(Ph_3P)_3$,[571] with $NaBH_4$,[572] or even with $LiAlH_4$, though with the last-mentioned reagent diols are the more usual product. With a BINOL–AlHOEt complex, however, reduction to the lactone proceeds smoothly.[573] With some reagents the reaction can be accomplished regioselectively, i.e., only a specific one of the two C=O groups of an unsymmetrical anhydride is reduced.[574] Open-chain anhydrides either are not reduced at all (e.g., with $NaBH_4$) or give 2 mol of alcohol. Lithium aluminium hydride usually reduces open-chain anhydrides to give 2 mol of alcohol. With cyclic anhydrides the reaction with $LiAlH_4$ can be controlled to give either diols or lactones.[575] With dropwise addition of methanol, $NaBH_4$ in THF reduces open-chain anhydrides to 1 mol of primary alcohol and 1 mol of carboxylic acid.[576]

Acyl halides are reduced[577] to alcohols by $LiAlH_4$ or $NaBH_4$, as well as by other metal hydrides (Table 19.5), but not by borane.

In general, reduction of amides to alcohols is difficult. More commonly the amide is reduced to an amine. An exception uses LiH_2NBH_3 to give the alcohol.[578] Reduction with sodium metal in propanol also gives the alcohol.[579] Acyl imidazoles are also reduced to the corresponding alcohol with $NaBH_4$ in aqueous HC1.[580]

There are no *Organic Syntheses* references, but see OS **II,** 526, for a related reaction. See OS **VI,** 482 for reduction to alcohols and OS IV, 271 for reduction of acyl halides.

19-38 *Reduction of Carboxylic Esters to Alcohols*

DIHYDRO,HYDROXY-DE-OXO,ALKOXY-TERSUBSTITUTION

$$RCOOR' \xrightarrow{LiAlH_4} RCH_2OH + R'OH$$

Lithium aluminium hydride reduces carboxylic esters to give 2 mol of alcohol.[581] The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining R'OH, this is a method of "hydrolyzing" esters. Lactones yield diols. Among the reagents that give the same products[582] are DIBAL-H, lithium triethylborohydride, and BH_3– SMe_2 in refluxing THF.[583] The $NaBH_4$ reduces phenolic esters, especially those containing electron-withdrawing groups,[584] but its reaction with other esters is usually so slow that such reactions are seldom feasible (though exceptions are known[585]), and it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. However, $NaBH_4$ reduces esters in the presence of certain compounds (see Table 19.5).[586] Carboxylic esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,[587] though high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations. Before the discovery of $LiAlH_4$, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault–Blanc procedure.* This procedure is still sometimes used where selectivity is necessary. See also **19-36,19-39,** and **10-86.**

OS II, 154, 325, 372, 468; **III,** 671; **IV,** 834; **VI,** 781; **VII,** 356; **VIII,** 155; **IX,** 251.

19-39 *Reduction of Carboxylic Acids and Esters to Alkanes*

TRIHYDRO-DE-ALKOXY,OXO-TERSUBSTITUTION, AND SO ON

$$RCOOR' \xrightarrow{(C_5H_5)_2TiCl_2} RCH_3 + R'OH$$

The reagent titanocene dichloride reduces carboxylic esters in a different manner from that of 10-86, 19-36, or 19-38. The products are the alkane RCH_3 and the alcohol R'OH.[533] The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).[588] The following sequence has been suggested:[588]

$$ArCOOH \xrightarrow{SiHCl_3} (ArCO)_2O \xrightarrow[R_3N]{SiHCl_3} ArCH_2SiCl_3 \xrightarrow[MeOH]{KOH} ArCH_3$$

Esters of aromatic acids are not reduced by this procedure, so an aromatic COOH group can be reduced in the presence of a COOR' group.[589] However, it is also possible to reduce aromatic ester groups, by a variation of the trichlorosilane procedure.[590] The *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols ($HOC_6H_4CH_3$) with sodium bis(2-methoxyethoxy)aluminum hydride, $NaAlH_2(OC_2H_4OMe)_2$ (*Red-Al*).[591]

Carboxylic acids can also be converted to alkanes, indirectly,[592] by reduction of the corresponding tosylhydrazides ($RCONHNH_2$) with $LiAlH_4$ or borane.[593]

OS VI, 747.

19-40 *Complete Reduction of Epoxides*

$$\underset{\text{R O H}}{\overset{\text{R}\quad\text{R''}}{\diagdown\ /}\ C-C} \xrightarrow{(C_5H_5)_2TiCl_2} \underset{\text{R'}-CH-CH_2-\text{R''}}{\text{R}}$$

Though the usual product of epoxide reductions is the alcohol (10-85), epoxides are reduced all the way to the alkane by titanocene dichloride[533] and by $Et_3SiH{-}BH_3$.[594]

19-41 *Reduction of Nitro Compounds to Amines*

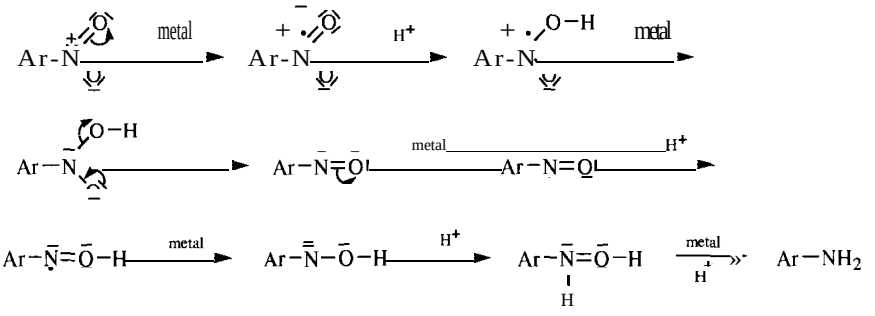
$$RNO_2 \xrightarrow[HCl]{Zn} RNH_2$$

Both aliphatic[595] and aromatic nitro compounds can be reduced to amines, though the reaction has been applied much more often to aromatic nitro compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, the most common being Zn, Sn, or Fe (or sometimes other metals) and acid, and catalytic hydrogenation.[596] Indium metal in aqueous ethanol with ammonium chloride also reduces aromatic nitro compounds to the corresponding aniline derivative.[597] Samarium and a catalytic amount of iodine also accomplishes this reduction.[598] A mild reduction uses Al(Hg) in aqueous THF with ultrasound.[599]

Among other reagents used[600] have been $Et_3SiH/RhCl(PPh_3)_3$,[601] AlH_3—$AlCl_3$, formic acid and Pd—C,[602] and sulfides such as NaHS, $(NH_4)_2S$, or polysulfides. The reaction with sulfides or polysulfides is called the *Zinin reduction.*[603] The $LiAlH_4$ reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds **(19-59).** Most metal hydrides, including $NaBH_4$ and BH_3, do not reduce nitro groups at all, though both aliphatic and aromatic nitro compounds have been reduced to amines with $NaBH_4$ and various catalysts, such as $NiCl_2$ or $CoCl_2$.[604] Borohydride exchange resin in the presence of $Ni(OAc)_2$, however, gives the amine.[605] Treatment of aromatic nitro compounds with $NaBH_4$ alone has resulted in reduction of the *ring* to a cyclohexane ring with the nitro group still intact[606] or in cleavage of the nitro group from the ring.[607] With $(NH_4)_2S$ or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.[608] The nitro groups of N-nitro compounds can also be reduced to amino groups, for example, nitrourea ($NH_2CONHNO_2$) gives semicarbazide (NH_2 $CONHNH_2$). Bakers yeast reduces aromatic nitro compounds to aniline derivatives.[609]

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines **(19-42),** hydrazobenzenes, azobenzenes **(19-59),** and azoxybenzenes **(19-58)** can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates. Reduction by metals in mineral acids cannot be stopped, but always produces the amine. Amines are also the products when nitro compounds, both alkyl and aryl, are reduced with $HCOONH_4$—Pd—C.[610] Many other functional groups (e.g., COOH, COOR, CN, amide) are not affected by this reagent (though ketones are reduced, see **19-33).** With optically active alkyl substrates this method gives retention of configuration.[611]

The mechanisms of these reductions have been very little studied, though it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents **(19-43),** and hydroxylamines can be isolated **(19-42).** With metals and acid the following path has been suggested:[612]



Certain aromatic nitroso compounds (Ar—NO) can be obtained in good yields by irradiation of the corresponding nitro compounds in 0.1 *M* aqueous KCN with UV light.[613] The reaction has also been performed electrochemically.[614] When nitro

compounds are treated with most reducing agents, nitroso compounds are either not formed or react further under the reaction conditions and cannot be isolated.

OS **I**, 52, 240, 455, 485; II, 130, 160, 175, 254, 447, 471, 501, 617; **III,** 56, 59, 63, 69, 73, 82, 86, 239, 242, 453; IV, 31, 357; V, 30, 346, 552, 567, 829, 1067, 1130.

19-42 *Reduction of Nitro Compounds to Hydroxylamines*

$$ArNO_2 \xrightarrow[H_2O]{Zn} ArNHOH$$

When aromatic nitro compounds are reduced with zinc and water under neutral conditions,[615] hydroxylamines are formed. Among other reagents used for this purpose have been SmI_2,[616] N_2H_4—Rh—C,[617] and $KBH_4/BiCl_3$.[618] Borane in THF reduces aliphatic nitro compounds (in the form of their salts) to hydroxylamines:[619]

$$R-\underset{R}{\overset{|}{\bar{C}}}-NO_2 \xrightarrow{BF_3\text{-}THF} R-\underset{R}{\overset{|}{CH}}-NHOH$$

Nitro compounds have been reduced electrochemically, to hydroxylamines as well as to other products.[620]

OS **I,** 445; **III,** 668; **IV,** 148; **VI,** 803; **VIII, 16.**

19-43 *Reduction of Nitroso Compounds and Hydroxylamines to Amines*

N-Dihydro-de-oxo-bisubstitution $\quad RNO \xrightarrow[HCl]{Zn} RNH_2$

N-Hydro-de-hydroxylation or *N*-Dehydroxylation $\quad RNHOH \xrightarrow[HCl]{Zn} RNH_2$

Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents that reduce nitro compounds **(19-41).** One example reduces a hydroxylamine to the amine with CS_2 in acetonitrile.[621] N-Nitroso compounds are similarly reduced to hydrazines:[622]

$$R_2N-NO \longrightarrow R_2N-NH_2$$

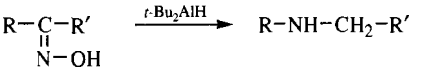
OS I, 511; II, 33, 202, 211, 418; **III,** 91; IV, 247. See also OS **VIII, 93.**

19-44 *Reduction of Oximes to Primary Amines or Aziridines*

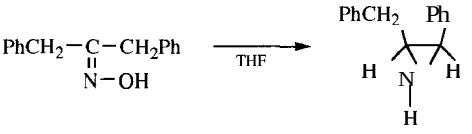
$$R-\underset{\underset{N-OH}{\overset{\|}{C}}}{\overset{}{}}-R' \xrightarrow{LiAlH_4} R-\underset{NH_2}{\overset{|}{CH}}-R'$$

Both aldoximes and ketoximes can be reduced to primary amines with $LiAlH_4$. The reaction is slower than with ketones, so that, for example, PhCOCH=NOH gave 34% PhCHOHCH=NOH.[623] Among other reducing agents that give this reduction[624] are zinc and acetic acid, sodium ethoxide, BH_3,[625] $NaBH_3CN$–$TiCl_3$,[626] and sodium and an alcohol.[627] Catalytic hydrogenation is also effective.[628] The reduction has been performed enantioselectively with baker's yeast[629] and with Ph_2SiH_2 and an optically active rhodium-complex catalyst.[630]

When the reducing agent is DIBAL-H, the product is a secondary amine, arising from a rearrangement:[631]



With certain oximes (e.g., those of the type $ArCH_2CR{=}NOH$), treatment with $LiAlH_4$ gives aziridines,[632] for example,



Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including Zn–HCl and H_2 and Raney nickel.

Oximes have been reduced in a different way, to give imines ($RR'C{=}NOH \rightarrow RR'C{=}NH$), which are generally unstable but can be trapped to give useful products. Among reagents used for this purpose have been $Bu_3P{-}SPh_3$[633] and $Ru_3(CO)_{12}$.[634]

Oximes can also be reduced to hydroxylamines **(16-24).**

OS **II,** 318; **ffl,** 513; **V,** 32, 83, 373, 376.

19-45 *Reduction of Azides to Primary Amines*

N-DIHYDRO-DE-DIAZO-BISUBSTITUTION

$$RN_3 \xrightarrow{LiAlH_4} RNH_2$$

Azides are easily reduced to primary amines by $LiAlH_4$, as well as by a number of other reducing agents,[635] including $NaBH_4$, PPh_3 (with this reagent, the process is called the *Staudinger reaction*),[636] H_2 and a catalyst, $Bu_3SnH/PhSiH_3/AIBN$,[637] Mg or Ca in MeOH,[638] baker's yeast,[639] Sm/I_2,[640] $LiMe_2NBH_3$,[641] and tin complexes prepared from $SnCl_2$ or $Sn(SR)_2$.[642] This reaction, combined with $RX \rightarrow RN_3$ **(10-65),** is an important way of converting alkyl halides RX to primary amines RNH_2; in some cases the two procedures have been combined into one laboratory step.[643] Sulfonyl azides (RSO_2N_3) have been reduced to sulfonamides (RSO_2NH_2) by irradiation in isopropyl alcohol[644] and with NaH.[645]

OS V, 586; **VII,** 433.

19-46 *Reduction of Miscellaneous Nitrogen Compounds*

ISOCYANATE-METHYLAMINE TRANSFORMATION

$$R{-}N{=}C{=}O \xrightarrow{LiAlH_4} R{-}NH{-}CH_3$$

ISOTHIOCYANATE-METHYLAMINE TRANSFORMATION

$$R\text{-}N{=}C{=}S \xrightarrow{LiAlH_4} R\text{-}NH\text{-}CH3$$

N,N-DIHYDRO- ADDITION

$$\text{Ar-N=N-Ar} \xrightarrow[\text{catalyst}]{H_2} \text{Ar-NH-NH-Ar}$$

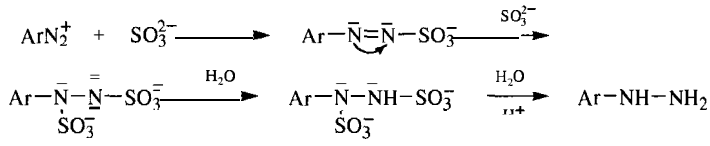
DIAZONIUM-ARYLHYDRAZONE REDUCTION

$$ArN_2^+\ Cl^- \xrightarrow{Na_2SO_3} ArNHNH_2$$

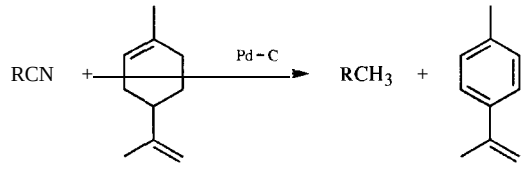
N-HYDRO-DE-NITROSO-SUBSTITUTION

$$R_2N{-}NO \xrightarrow[Ni]{H_2} R_2NH$$

Isocyanates and isothiocyanates are reduced to methylamines on treatment with $LiAlH_4$. Lithium aluminium hydride does not usually reduce azo compounds[646] (indeed these are the products from $LiAlH_4$ reduction of nitro compounds, **19-59),** but these can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide[647] (see **15-11).** Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism.[648]



The initial product is a salt of hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes **(14-24).** N-Nitrosoamines can be denitrosated to secondary amines by a number of reducing agents, including H2 and a catalyst,[649] BF_3—THF—$NaHCO_3$,[650] and $NaBH_4$—$TiCl_4$,[651] as well as by hydrolysis.[652]



A cyano group can be reduced to a methyl group by treatment with a terpene such as limonene (which acts as reducing agent) in the presence of palladium-charcoal.[653] H_2 is also effective,[654] though higher temperatures are required. The R group may be alkyl or aryl. Cyano groups CN have also been reduced to CH_2OH, in the vapor phase, with 2-propanol and zirconium oxide.[655]

OS I, 442; **III,** 475. Also see OS V, 43.

19-47 *Reduction of Sulfonyl Halides and Sulfonic Acids to Thiols*

$$RSO_2Cl \xrightarrow{LiAlH_4} RSH$$

Thiols can be prepared by the reduction of sulfonyl halides[656] with $LiAlH_4$. Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and

HI, also give the reduction. Sulfonic acids have been reduced to thiols with a mixture of triphenylphosphine and either I_2 or a diaryl disulfide.[657] Disulfides (RSSR) can also be produced.[658] For the reduction of sulfonyl chlorides to sulfinic acids, see **10-128.**

OS **I,** 504; **IV,** 695; **V,** 843.

B. *Reactions in Which an Oxygen Is Removed from the Substrate*

19-48 *Eduction of Amine Oxides and Azoxy Compounds*

N-OXYGEN-DETACHMENT

$$R_3\overset{+}{N}-O \xrightarrow{PPh_3} R3N$$

$$Ar\text{-}\overset{+}{N}(O^-)\text{=}N\text{-}Ar \xrightarrow{PPh_3} Ar-N=N-Ar$$

Amine oxides[659] and azoxy compounds (both alkyl and aryl)[660] can be reduced practically quantitatively with triphenylphosphine.[661] Other reducing agents (e.g., $LiAlH_4$, H_2-Ni, PCl_3, $TiCl_3$)[662] $TiCl_4$ with $LiAlH_4$, or $SbCl_2$ have also been used. Nitrile oxides[663] $R-C\equiv N^+-O^\theta$ can be reduced to nitriles with trialkylphosphines,[664] and isocyanates (RNCO) to isocyanides RNC with Cl_3SiH– Et_3N.[665]

OS IV, 166. See also OS **VIII, 57.**

19-49 *Reduction of Sulfoxides and Sulfones*

S-OXYGEN-DETACHMENT

$$R-\underset{\underset{O}{\|}}{S}-R \xrightarrow{LiAlH_4} R-S-R$$

Sulfoxides can be reduced to sulfides by many reagents,[666] among them $LiAlH_4$, HI, Bu_3SnH,[667] $MeSiCl_3$–NaI,[668] H_2–Pd–C,[669] $NaBH_4$–$NiCl_2$,[670] Ph_3P,[671] and SiO_2/$SOCl_2$. Sulfones, however, are usually stable to reducing agents, though they have been reduced to sulfides with DIBAL-H [$(i\text{-Bu})_2AlH$].[672] A less general reagent is $LiAlH_4$, which reduces some sulfones to sulfides, but not others.[673] Both sulfoxides and sulfones can be reduced by heating with sulfur (which is oxidized to SO_2), though the reaction with sulfoxides proceeds at a lower temperature. It has been shown by using substrate labeled with ^{35}S that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since about 75% of the original radioactivity of the sulfone is lost.[674] This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent.* There is no direct general method for the reduction of sulfones to sulfoxides, but an indirect method has been reported.[675] Selenoxides can be reduced to selenides with a number of reagents.[676]

OS IX, 446

19-50 *Reduction of Hydroperoxides and Peroxides*

$$R{-}O{-}O{-}H \xrightarrow{LiAlH_4} ROH$$

Hydroperoxides can be reduced to alcohols with $LiAlH_4$ or Ph_3P[677] or by catalytic hydrogenation. This functional group is very susceptible to catalytic hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.[678]

$$RR'CHCN \xrightarrow[-78\ ^\circ C]{LiN(i\text{-}Pr)_2} [RR'\bar{C}CN] \xrightarrow[-78\ ^\circ C]{O_2} RR'CCN(OO^-) \xrightarrow[2.\ Sn^{2+}]{1.\ H^+} RR'C(OH)CN \xrightarrow{OH^-} RR'CO$$

The reaction is an important step in a method for the oxidative decyanation of nitriles containing an a hydrogen.[679] The nitrile is first converted to the α-hydroperoxy nitrile by treatment with base at -78°C followed by O_2. The hydroperoxy nitrile is then reduced to the cyanohydrin, which is cleaved (the reverse of 16-51) to the corresponding ketone. The method is not successful for the preparation of aldehydes ($R' = H$).

Peroxides are cleaved to 2 mol of alcohols by $LiAlH_4$ or by catalytic hydrogenation. Peroxides can be reduced to ethers with $P(OEt)_3$.[680] In a similar reaction, disulfides (RSSR') can be converted to sulfides (RSR') by treatment with tris(diethylamino)phosphine, $(Et_2N)_3P$.[681]

OS VI, 130.

19-51 *Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles*

$$RCH_2NO_2 \xrightarrow[HOAc]{Zn} RCH{=}NOH$$

Nitro compounds that contain an a hydrogen can be reduced to oximes with zinc dust in HOAC[682] or with other reagents, among them CS_2–Et_3N,[683] $CrCl_2$,[684] and (for α-nitro sulfones) $NaNO_2$.[685] α-Nitro alkenes have been converted to oximes ($-C=C-NO_2 \rightarrow -CH-C=NOH$) with sodium hypophosphite and with Pb–HOAc–DMF, as well as with certain other reagents.[686]

$$RCH_2NO_2 \xrightarrow{NaBH_2S_3} RC{\equiv}N$$

Primary aliphatic nitro compounds can be reduced to nitriles with sodium dihydro(trithio)borate[584] or with *t*-BuN≡C/BuN=C=O.[687] Secondary compounds give mostly ketones (e.g., nitrocyclohexane gave 45% cyclohexanone, 30% cyclohexanone oxime, and 19% *N*-cyclohexylhydroxylamine). Tertiary aliphatic nitro compounds do not react with this reagent. See also 19-41.

OS IV, 932.

C. *Reduction with Cleavage*

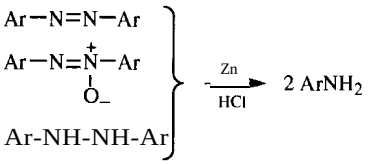
19-52 *de-Alkylation of Amines and Amides*

$$R_2'N{-}R \longrightarrow R_2'N{-}H$$

Certain amines can be dealkylated, usually under reductive conditions. N-Allyl amines ($R_2N{-}CH_2CH{=}CH_2$) are converted to the corresponding amine ($R_2N{-}H$) with DIBAL/$NiCl_2$dppp,[688] where diisobutylaluminum = DIBAL and 1,3-bis(diphenylphosphino)propane = dppp, and with $Pd(dba)_2$dppb.[689] A mixture of $TiCl_3$ and Li converts N-benzylamines to the amine ($R_2NCH_2Ph \rightarrow R_2NH$).[690] In the case of N,N-dimethyl amines, $RuCl_3$ and H_2O_2 demethylate the amine ($ArNMe_2 \rightarrow ArNHMe$).[691]

The process is not limited to amines. Amides can also be dealkylated. N-Benzyl amides are debenzylated in the presence of NBS and AIBN.[692]

19-53 *Reduction of Azo, Azoxy, and Hydrazo Compounds to Amines*



Azo, azoxy, and hydrazo compounds can all be reduced to amines.[693] Metals (notably zinc) and acids, and $Na_2S_2O_4$, are frequently used as reducing agents. Borane reduces azo compounds to amines, though it does not reduce nitro compounds.[694] Lithium aluminum hydride does not reduce hydrazo compounds or azo compounds, though with the latter, hydrazo compounds are sometimes isolated. With azoxy compounds, $LiAlH_4$ gives only azo compounds (19-48).

OS I, 49; II, 35, 39; III, 360. Also see OS II, 290.

19-54 *Reduction of Disulfides to Thiols*

S-HYDROGEN-UNCOUPLING

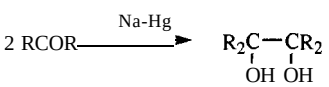
Disulfides can be reduced to thiols by mild reducing agents,[695] such as zinc and dilute acid or Ph_3P and H_2O.[696] The reaction can also be accomplished simply by heating with alkali.[697] Among other reagents used have been $LiAlH_4$, Mg/MeOH,[698] $KBH(O{-}i{-}Pr)_3$,[699] and hydrazine or substituted hydrazines.[700]

OS II, 580. Also see OS IV, 295.

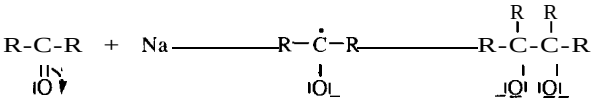
D. *Reductive Coupling*

19-55 *Bimolecular Reduction of Aldehydes and Ketones to 1,2-Diols*

2/*O*-HYDROGEN-COUPLING

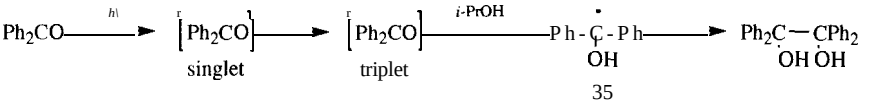


1,2-Diols (pinacols) can be synthesized by reduction of aldehydes and ketones with active metals such as sodium, magnesium, or aluminum.[701] Aromatic ketones give better yields than aliphatic ones. The use of a $Mg-MgI_2$ mixture has been called the *Gomberg–Bachmann pinacol synthesis.* As with a number of other reactions involving sodium, there is a direct electron transfer here, converting the ketone or aldehyde to a **ketyl**, which dimerizes.



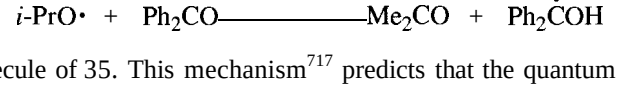
Other reagents have been used,[702] including SmI_2,[703] Yb,[704] activated Mn,[705] In with ultrasound,[706] $VCl_3(thf)_3/Zn$,[707] and a reagent prepared from $TiCl_4$ and Mg amalgam[708] (a low-valent titanium reagent; see 19-56). Dialdehydes have been cyclized by this reaction (with $TiCl_3$) to give cyclic 1,2-diols in good yield.[709] Unsymmetrical coupling between two different aldehydes has been achieved by the use of a vanadium complex,[710] while $TiCl_3$ in aqueous solution has been used to couple two different ketones.[711] Two aldehydes have also been coupled using magnesium in water.[712] Coupling leads to a mixture of syn- and anti-diols. "Syn-selective" reagents are Cp_2TiCl_2/Mn[713] and $NbCl_3$.[714]

The dimerization of ketones to 1,2-diols can also be accomplished photochemically; indeed, this is one of the most common photochemical reactions.[715] The substrate, which is usually a diaryl or aryl alkyl ketone (though a few aromatic aldehydes and dialkyl ketones have been dimerized), is irradiated with UV light in the presence of a hydrogen donor such as isopropyl alcohol, toluene, or an amine.[716] In the case of benzophenone, irradiated in the presence of 2-propanol, the ketone molecule initially undergoes $n \rightarrow n^*$ excitation, and the singlet species thus formed crosses to the T_1 state with a very high efficiency.



35

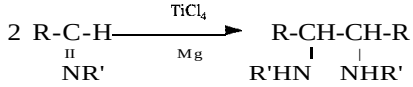
The T_1 species abstracts hydrogen from the alcohol (p. 321), and then dimerizes. The *i*-PrO· radical, which is formed by this process, donates H· to another molecule of ground-state benzophenone, producing acetone and



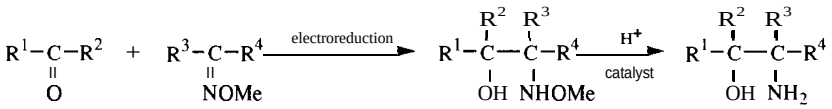
another molecule of 35. This mechanism[717] predicts that the quantum yield for the disappearance of benzophenone should be 2, since each quantum of light results in the conversion of 2 mol of benzophenone to 35. Under favorable experimental conditions the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in 2-propanol (though *p*-aminobenzophenone, e.g., can be dimerized in cyclohexane[718]). The reaction has also been carried out electrochemically.[719]

A radical-induced coupling of an α,ω-dialdehyde led to *cis*-1,2-cyclopentanediol when treated with Bu_3SnH and AIBN.[720] or induced photochemically.[721]

In a similar type of process, imines have been dimerized to give 1,2-diamines, by a number of procedures, including treatment with $TiCl_4$–Mg,[722] In / aqueous EtOH,[723] Zn / aqueous NaOH,[724] Cp_2VCl_2 / Zn / $PhMe_2SiCl$,[725] with SmI_2,[726] and (for silylated imines) $NbCl_4(thf)_2$.[727] When electroreduction was used, it was even



possible to obtain cross-products, by coupling a ketone to an O-methyl oxime:[728]

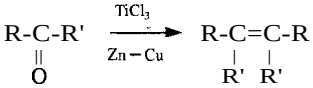


The *N*-methoxyamino alcohol could then be reduced to the amino alcohol.[728]

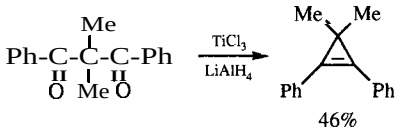
OS I, 459; II, 71. For diamines, OS 76, 23

19-56 *Bimolecular Reduction of Aldehydes or Ketones to Alkenes*

DE-OXYGEN-COUPLING

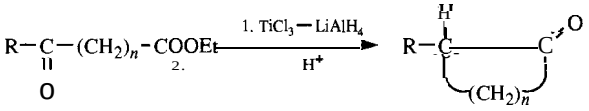


Aldehydes and ketones, both aromatic and aliphatic (including cyclic ketones), can be converted in high yields to dimeric alkenes by treatment with $TiCl_3$ and a zinc-copper couple.[729] This is called the *McMurry reaction*.[730] The reagent produced in this way is called a *low-valent titanium reagent*, and the reaction has also been accomplished[731] with low-valent titanium reagents prepared in other ways, for example, from Mg and a $TiCl_3$–THF complex,[732] from $TiCl_4$ and Zn or Mg,[733] from $TiCl_3$ and $LiAlH_4$,[734] from $TiCl_3$ and lamellar potassium graphite,[735] from $TiCl_3$ and K or Li,[736] as well as with Zn–Me_3SiCl[737] and with certain compounds prepared from WCl_6 and either lithium, lithium iodide, $LiAlH_4$, or an alkyllithium (see 17-17).[738] The reaction has been used to convert dialdehydes and diketones to cycloalkenes.[739] Rings of 3-16 and 22 members have been closed in this way, for example,[740]



46%

The same reaction on a keto ester gives a cycloalkanone.[741]

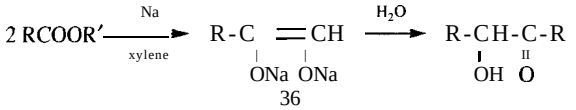


Indoles have been prepared form *o*-acyl amides with Ti(powder) and Me_3SiCl[742] or with $TiCl_3$—C_8K.[743] Benzofurans have been prepared by a closely related reaction.[744]

Unsymmetrical alkenes can be prepared from a mixture of two ketones, if one is in excess.[745] The mechanism consists of initial coupling of two radical species to give a 1,2-dioxygen compound (a titanium pinacolate), which is then deoxygenated.[746]

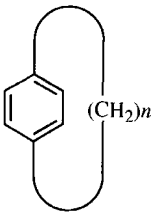
OS VII, 1.

19-57 *Acyloin Ester Condensation*

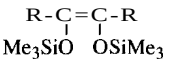


36

When carboxylic esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place, and the product is an α-hydroxy ketone (called an acyloin).[747] The reaction, called the *acyloin ester condensation*,[748] is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way, for example, $R = C_{17}H_{35}$, but for high molecular weight esters, toluene or xylene is used as the solvent. The acyloin condensation has been used with great success, in boiling xylene, to prepare cyclic acyloins from diesters.[749] The yields are 50-60% for the preparation of 6- and 7-membered rings, 30-40% for 8- and 19-membered, and 60-95% for rings of 10-20 members. Even larger rings have been closed in this manner. This is one of the best ways of closing rings of 10 members or more. The reaction has been used to close four-membered rings,[750] though this is generally not successful. The presence of double or triple bonds does not interfere.[751] Even a benzene ring can be present, and many paracyclophane derivatives (37) with $n = 9$ or more have been synthesized in this manner.[752]



37

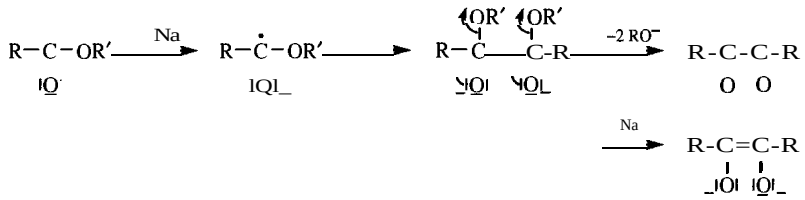


38

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane Me_3SiCl, in which case the dianion 36 is converted to the bis silyl enol ether 38, which can be isolated and subsequently hydrolyzed to the acyloin with aqueous acid.[753] This is now the standard way to conduct the acyloin condensation. Among other things, this method inhibits the Dieckmann condensation[754] **(10-118),** which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed (note that the ring formed by a Dieckmann condensation is always one carbon atom smaller than that formed by an acyloin condensation of the same substrate). The Me_3SiCl method

is especially good for the closing of four-membered rings.[755] Yields of four-, five-, and six-membered rings are improved by the use of ultrasound.[756]

The mechanism is not known with certainty, but it is usually presumed that the diketone RCOCOR is an intermediate,[757] since small amounts of it are usually isolated as side products, and when it is resistant to reduction (e.g., *t*-Bu—COCO—*t*-Bu), it is the major product. A possible sequence (analogous to that of 19-55) is:



In order to account for the ready formation of large rings, which means that the two ends of the chain must approach each other even though this is conformationally unfavorable for long chains, it may be postulated that the two ends become attached to nearby sites on the surface[758] of the sodium.

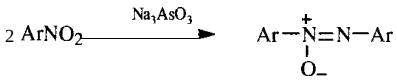
In a related reaction, aromatic carboxylic acids were condensed to α-diketones (2 ArCOOH → ArCOCOAr) on treatment with excess Li in dry THF in the presence of ultrasound.[759]

The acyloin condensation was used in an ingenious manner to prepare the first reported catenane (see p. 113).[760] This synthesis of a catenane produced only a small yield and relied on chance for threading the molecules before ring closure.

OS II, 114; IV, 840; VI, 167.

19-58 *Reduction of Nitro to Azoxy Compounds*

NITRO-AZOXY REDUCTIVE TRANSFORMATION

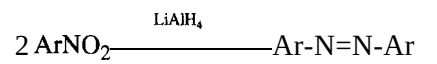


Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, NaTeH,[761] $NaBH_4$—PhTeTePh,[762] and glucose. The most probable mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (**19-42**), and these combine (12-51). The combination step is rapid compared to the reduction process.[763] Nitroso compounds can be reduced to azoxy compounds with triethyl phosphite or triphenylphosphine[764] or with an alkaline aqueous solution of an alcohol.[765]

OS II, 57.

19-59 *Reduction of Nitro to Azo Compounds*

N-DE-BISOXYGEN-COUPLING



Nitro compounds can be reduced to azo compounds with various reducing agents, of which $LiAlH_4$ and zinc and alkali are the most common. With many of these reagents, slight differences in conditions can lead either to the azo or azoxy **(19-58)** compound. Analogously to **19-58,** this reaction may be looked on as a combination of $ArN{=}O$ and $ArNH_2$ **(12-50).** However, when the reducing agent was $NaBH_4$,[766] it was shown that azoxy compounds were intermediates. Nitroso compounds can be reduced to azo compounds with $LiAlH_4$.

Nitro compounds can be further reduced to hydrazo compounds with zinc and sodium hydroxide, with hydrazine hydrate and Raney nickel,[767] or with $LiAlH_4$ mixed with a metal chloride such as $TiCl_4$ or VCl_3.[768] The reduction has also been accomplished electrochemically.

OS HI, 103.

Reactions in Which an Organic Substrate Is Both Oxidized and Reduced

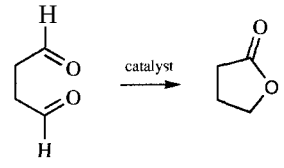
Some reactions that belong in this category have been considered in earlier chapters. Among these are the Tollens' condensation **(16-46),** the benzil-benzilic acid rearrangement (18-6), and the Wallach rearrangement **(18-43).**

19-60 *The Cannizzaro Reaction*

CANNIZZARO ALDEHYDE DISPROPORTIONATION

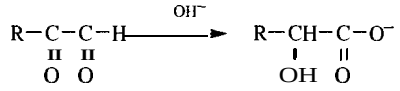
$$2\ ArCHO \xrightarrow{NaOH} ArCH_2OH + ArCOO^-$$

Aromatic aldehydes, and aliphatic ones with no a hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.[769] In this reaction, one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an a hydrogen do not give the reaction, because when these compounds are treated with base the aldol reaction **(16-38)** is much faster.[770] Normally, the best yield of acid or alcohol is 50% each, but this can be altered in certain cases. When the aldehyde contains a hydroxide group in the ring, excess base oxidizes the alcohol formed and the acid can be prepared in high yield (the OH^- is reduced to H_2). On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde. In this case, the formaldehyde reduces the aldehyde to alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed Cannizzaro reaction*.[771] The Tollens' condensation **(16-46)** includes a crossed Cannizzaro reaction as its last step. A Cannizzaro reaction run on 1,4-dialdehydes (note that a hydrogens are present here) with a rhodium phosphine complex catalyst gives ring closure, for example,[772]



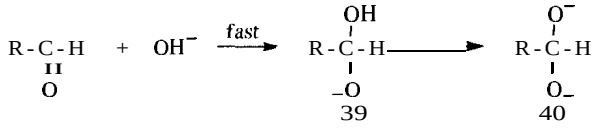
The product is the lactone derived from the hydroxy acid that would result from a normal Cannizzaro reaction.

α-Keto aldehydes give internal Cannizzaro reactions:

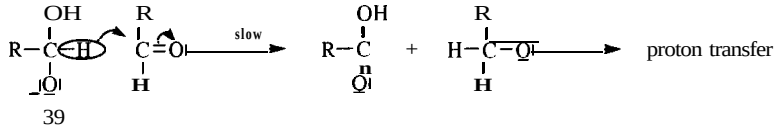


This product is also obtained on alkaline hydrolysis of compounds of the formula $RCOCHX_2$. Similar reactions have been performed on α-keto acetals[773] and γ-keto aldehydes.

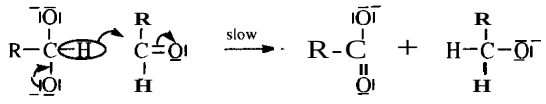
The mechanism[774] of the Cannizzaro reaction[775] involves a hydride shift (an example of mechanism type 2, p. 1508). First, OH~adds to the C=O to give 39, which may lose a proton in the basic solution to give the di-ion 40.



The strong electron-donating character of O^- greatly facilitates the ability of the aldehydic hydrogen to leave with its electron pair. Of course, this effect is even stronger in 40. When the hydride does leave, it attacks another molecule of aldehyde. The hydride can come from 39 or 40:



39



40

If the hydride ion comes from 39, the final step is a rapid proton transfer. In the other case, the acid salt is formed directly, and the alkoxide ion acquires a proton from the solvent. Evidence for this mechanism is (1) The reaction can be first order in base and second order in substrate (thus going through 39) or, at higher base concentrations, second order in each (going through 40); and (2) when the reaction was run in D_2O, the recovered alcohol contained no a deuterium,[776] indicating that the hydrogen comes from another mole of aldehyde and not from the medium.[777]

OS I, 276; II, 590; III, 538; IV, 110.

19-61 *The Tishchenko Reaction*

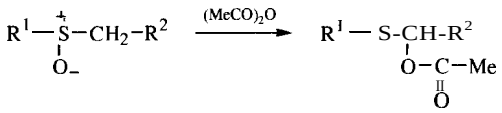
TISHCHENKO **ALDEHYDE-ESTER DISPROPORTIONATION**

When aldehydes, with or without a hydrogen, are treated with aluminum ethoxide, one molecule is oxidized and another reduced, as in **19-60,** but here they are found as the ester. The process is called the *Tishchenko reaction.* Crossed Tishchenko reactions are also possible. With more strongly basic alkoxides, such as magnesium or sodium alkoxides, aldehydes with an a hydrogen give the aldol reaction. Like **19-60,** this reaction has a mechanism that involves hydride transfer.[778] The Tishchenko reaction can also be catalyzed[779] by ruthenium complexes,[780] by Cp_2ZrH_2[781] or $BuTi(O\text{—}i\text{-}Pr)_4Li$,[782] and, for aromatic aldehydes, by di sodium tetracarbonylferrate, $Na_2Fe(CO)_4$.[783]

OS I, 104.

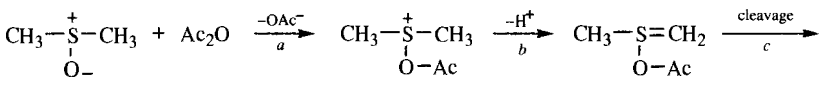
19-62 *The Pummerer Rearrangement*

PUMMERER METHYL SULFOXIDE REARRANGEMENT

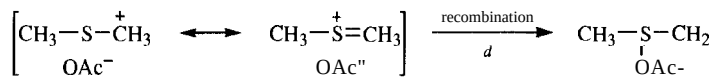


When sulfoxides bearing an a hydrogen are treated with acetic anhydride, the product is an α-acetoxy sulfide. This is one example of *the Pummerer rearrangement,* in which the sulfur is reduced while an adjacent carbon is oxidized.[784] The product is readily hydrolyzed **(10-6)** to the aldehyde R_2CHO.[785] Besides acetic anhydride, other anhydrides and acyl halides give similar products. Inorganic acids such as HC1 also give the reaction, and $RSOCH_2R'$ can be converted to RSCHC1R' in this way. Sulfoxides can also be converted to α-halo sulfides[786] by other reagents, including sulfuryl chloride, NBS, and NCS. Enantioselective Pummerer rearrangements are known.[787] Uncatalyzed thermal rearrangements are also known.[788]

The following four-step mechanism has been proposed for the reaction between acetic anhydride and DMSO:[789]



41



For DMSO and acetic anhydride, step d is intermolecular, as shown by ^{18}O isotopic labeling studies.[790] With other substrates, however, step d can be inter- or intramolecular, depending on the structure of the sulfoxide.[791] Depending on the substrate and reagent, any of the first three steps can be rate-determining. In the case of Me_2SO treated with $(F_3CCO)_2O$ the intermediate corresponding to 41[792] could be isolated at low temperature, and on warming gave the expected product.[793] There is much other evidence for this mechanism.[794]

19-63 *The Willgerodt Reaction*

WILLGERODT CARBONYL TRANSFORMATION

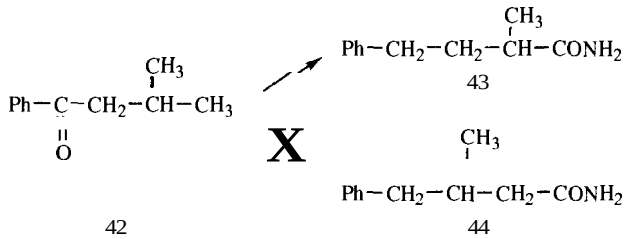
$$ArCOCH_3 \xrightarrow{(NH_4)_2S_X} ArCH_2CONH_2 + ArCH_2COO^- NH_4^+$$

In the *Willgerodt reaction*, a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.[795] The carbonyl group of the product is always at the end of the chain. Thus $ArCOCH_2CH_3$ gives the amide and the salt of $ArCH_2CH_2COOH$, and $ArCOCH_2CH_2CH_3$ gives derivatives of $ArCH_2CH_2CH_2COOH$. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinylic and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. Unlike the Pummerer rearrangement (19-62), which involves transposition of an oxygen from S to C, the Willgerodt reaction involves oxygen migration *and* oxidation of the organic species. The use of sulfur and a dry primary or secondary amine (or ammonia) as the reagent is called the *Kindler modification* of the Willgerodt reaction.[796] The product in this case is $Ar(CH_2)_nCSNR_2$,[797] which can be hydrolyzed to the acid. Particularly good results are obtained with morpholine as the amine. For volatile amines the HCl salts can be used instead, with NaOAc in DMF at 100°C.[798] Dimethylamine has also been used in the form of dimethylammonium dimethylcarbamate ($Me_2NCOOMe_2NH_2^+$.[799]) The Kindler modification has also been applied to aliphatic ketones.[800]

Alkyl aryl ketones can be converted to arylacetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with silver nitrate and I_2 or Br_2,[801] or with thallium nitrate, MeOH, and trimethyl orthoformate adsorbed on Montmorillonite K-10 clay, an acidic clay.[802]

$$ArCOCH_2R \xrightarrow[I_2 \text{ or } Br_2]{AgNO_3} Ar-\underset{\displaystyle R}{\underset{|}{CH}}-COOCH_3 \qquad R = H, Me, Et$$

The mechanism of the Willgerodt reaction is not completely known, but some conceivable mechanisms can be excluded. Thus, one might suppose that the alkyl group becomes completely detached from the ring and then attacks it with its other end. However, this possibility is ruled out by experiments such as the following: When isobutyl phenyl ketone (42) is subjected to the Willgerodt reaction, the product is 43, not 44, which would arise if the end carbon of the ketone became bonded to the ring in the product:[803]



42 43 44

This also excludes a cyclic-intermediate mechanism similar to that of the Claisen rearrangement (18-33). Another important fact is that the reaction is successful for singly branched side chains, such as 42, but not for doubly branched side chains, as in $PhCOCMe_3$.[803] Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus $PhCOCH_2CH_3$, $PhCH_2COMe$, and $PhCH_2CH_2CHO$ all give $PhCH_2CH_2CONH_2$.[804] All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain, though just what form these take is not certain. Initial reduction to the hydrocarbon can be ruled out, since alkylbenzenes do not give the reaction. In certain cases, imines[805] or enamines[806] have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

APPENDIX A

The Literature of Organic Chemistry

All discoveries in the laboratory must be published somewhere if the information is to be made generally available. A new experimental result that is not published might as well not have been obtained, insofar as it benefits the entire chemical world. The total body of chemical knowledge (called *the literature)* is located on the combined shelves of all the chemical libraries in the world. Anyone who wishes to learn whether the answer to any chemical question is known, and, if so, what the answer is, has only to turn to the contents of these shelves. Indeed the very expressions "is known", "has been done" and so on, really mean "has been published". To the uninitiated, the contents of the shelves may appear formidably large, but fortunately the process of extracting information from the literature of organic chemistry is usually not difficult. In this appendix, we shall examine the literature of organic chemistry, confining our attention chiefly to the results of laboratory work, rather than those of industrial organic chemistry.[1] The literature can be divided into two broad categories: primary sources and secondary sources. A *primary source* publishes the original results of laboratory investigations. Books, indexes, and other publications that cover material that has previously been published in primary sources are called *secondary sources.* It is because of the excellence of the secondary sources in organic chemistry (especially Chemical *Abstracts* and Beilstein) that literature searching is comparatively not difficult. The two chief kinds of primary source are journals and patents. There are several types of secondary source.

PRIMARY SOURCES

Journals

For well over 100 years, nearly all new work in organic chemistry (except for that disclosed in patents) has been published in journals. There are thousands of journals that publish chemical papers, in many countries and in many languages. Some print papers covering all fields of science; some are restricted to chemistry; some to organic chemistry; and some are still more specialized. Fortunately for the sanity of organic chemists, the vast majority of important papers in "pure" organic chemistry (as opposed to "applied") are published in relatively few journals, perhaps 50 or fewer. Of course, this is still a large number, especially since some are published

weekly and some semimonthly, but it is considerably smaller than the total number of journals (perhaps as high as 10,000) that publish chemical articles.

In addition to ordinary papers, there are two other types of publications in which original work is reported: *notes* and *communications*. A note is a brief paper, often without a summary (nearly all papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper.[2] Communications (also called *letters)* are also brief and usually without summaries (though some journals now publish summaries along with their communications, a welcome trend). However, communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually, they include only the most important experimental details or none at all.
2. They are of immediate significance. Journals that publish communications make every effort to have them appear as soon as possible after they are received. Some papers and notes are of great importance, and some are of lesser importance, but all communications are supposed to be of high importance.
3. Communications are preliminary reports, and the material in them may be republished as papers at a later date, in contrast to the material in papers and notes, which cannot be republished.

Although papers (we use the term in its general sense, to cover notes and communications also) are published in many languages, the English-speaking chemist is in a fairly fortunate position. At present, well over one-half of the important papers in organic chemistry are published in English. Not only are American, British, and British Commonwealth journals published almost entirely in English, but so are many others around the world. There are predominantly English-language journals published in Japan, Italy, Czech Republic and other countries. In a recent reorganization, six prominent European journals *(Chemische Berichte, Liebigs Annalen der Chemie, Bulletin de la Societe Chimique de France, Bulletin des Societes Chimique Beiges, Recueil des Travaux Chimiques des Pays-Bas, and Gazzetta Chimica Italiana)* have been discontinued. In their place is the *European Journal of Organic Chemistry,* published in English. Most of the articles published in other languages have summaries printed in English also. Furthermore, the second most important language (in terms of the number of organic chemical papers published) was Russian, and most of these papers are available in English translation, though in most cases, 6 months to 1 year later. With the political changes in Russia, however, many of these journals have been modified or discontinued. A considerable number of important papers are published in German and French; these are generally not available in translation, so that the organic chemist should have at least a reading knowledge of these languages. An exception is the journal *Angewandte Chemie,* which in 1962 became available in English under the title *Angewandte Chemie International* edition in English. Of course, a reading knowledge of French and German (especially German) is even more important for the older literature. Before $\sim$1920, more than one-half of the important

chemical papers were in these languages. It must be realized that the original literature is never obsolete. Secondary sources become superseded or outdated, but nineteenth century journals are found in most chemical libraries and are still consulted. Table A.1 presents a list of the more important current journals that publish original papers[3] and communications in organic chemistry. Some of them also publish review articles, book reviews, and other material. Changes in journal title have not been infrequent; footnotes to the table indicate some of the more important, but some of the other journals listed have also undergone title changes. In 1999, the *Journal of Organic Chemistry* stopped publishing communications, and these are now published in a new journal, *Organic Letters.*

The primary literature has grown so much in recent years that attempts have been made to reduce the volume. One such attempt is the *Journal of Chemical Research,* begun in 1977. The main section of this journal, called the "Synopses", publishes synopses, which are essentially long abstracts, with references. The full texts of most of the papers are published only in microfiche and miniprint versions. For some years, the American Chemical Society journals, including/ *Am. Chem. Soc. and J. Org. Chem.*, have provided supplementary material for some of their papers. This material is available from the Microforms and Back Issues Office at the ACS Washington office, either on microfiche or as a photocopy. These practices have not yet succeeded in substantially reducing the total volume of the world's primary chemical literature.

Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures), as long as the compounds are useful. It comes as a surprise to many to learn that a substantial proportion of the patents granted (perhaps 20-30%) are chemical patents. Chemical patents are part of the chemical literature, and both U.S. and foreign patents are regularly abstracted by *Chemical Abstracts.* In addition to learning about the contents of patents from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office, which, published weekly and available in many libraries, lists titles of all patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Photocopies of any U.S. patent and most foreign patents can be obtained at low cost from the U.S. Patent and Trademark Office, Washington, DC, 20231. In addition, *Chemical Abstracts* lists, in the introduction to the first issue of each volume, instructions for obtaining patents from 26 countries.

Although patents are often very useful to the laboratory chemist, and no literature search is complete that neglects relevant patents, as a rule they are not as reliable as papers. There are two reasons for this:

1. It is in the interest of the inventor to claim as much as possible. Therefore he or she may, for example, actually have carried out a reaction with ethanol and

with 1-propanol, but will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol that the inventor did not use may find that the reaction gives no yield at all. In general, it is safest to duplicate the actual examples given, of which most chemical patents contain one or more.

2. Although legally a patent gives an inventor a monopoly, any alleged infringements must be protected in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. This practice is not exactly cricket, because a patent is supposed to be a full disclosure, but patent attorneys are generally

skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

Fortunately, the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in every paper in a journal. In general, however, the laboratory chemist must be more wary of patents than of papers.

SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if this were all, if there were no indexes, abstracts, review articles, and other secondary sources, the literature would be unusable because it is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. There are various kinds and the categories tend to merge. Our classification is somewhat arbitrary.

Listings of Titles

The profusion of original papers is so great that publications merely listing the titles of current papers find much use. Such lists are primarily methods of alerting the chemist to useful papers published in journals that he or she does not normally read. There are two "title" publications covering the whole of chemistry. One of these, *Current Contents Physical, Chemical & Earth Sciences*,[12] which began in 1967 and appears weekly, contains the contents pages of all issues of ~ 800 journals in chemistry, physics, earth sciences, mathematics, and allied sciences. Each issue contains an index of important words taken from the titles of the papers listed in that issue, and an author index, which, however, lists only the first-named author of each paper. The author's address is also given, so that one may write for reprints. *Current Contents* is also available on computer disks, with "keywords"—words taken from the title and the interior of the paper. The disks can be searched for the keywords, allowing the user to find papers containing specific topics of interest.

The other "title" publication is *Chemical Titles*, published by chemical Abstracts Service. This biweekly publication, begun in 1961, lists, in English, all titles from more than 700 journals, all in the field of chemistry. The most useful aspect of this publication is the way the titles are given. They are listed in alphabetical order of *every word in the title*, except for such words as "the", "of", "investigation", "synthesis", and so on. (each issue contains a list of words prevented from indexing). This means that a title containing seven significant words is listed seven times. These words are also called "keywords". Furthermore, at each listing are given the words that immediately precede and follow the keyword. In the second section of each issue (called the Bibliography), the complete titles and the authors are given. Incidentally, this Bibliography duplicates, for the journals they both cover, the

listings in *Current Contents Physical, Chemical, & Earth Sciences,* since the complete contents of journals are given in order of page number. Each issue of *Chemical Titles* has an author index, covering all authors, not just the first author. Addresses are not given.

Abstracts

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. From the earliest days of organic chemistry, abstracts of papers have been widely available, often as sections of journals whose principal interests lay elsewhere.[13] At the present time, there are only two publications entirely devoted to abstracts covering the whole field of chemistry. One of these, *Referativnyi Zhurnal, Khimiya*, which began in 1953, is published in Russian and is chiefly of interest to Russian-speaking chemists. The other is *Chemical Abstracts.* This publication, which appears weekly, prints abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world.[14] Approximately 18,000 journals are covered, in many languages. In addition, *CA* publishes abstracts of every patent of chemical interest from 18 countries, including the United States, the United Kingdom, Germany, and Japan, as well as many patents from 8 additional countries. *Chemical Abstracts* lists and indexes but does not abstract review articles and books. The abstracts currently appear in 80 sections, of which sections 21–34 are devoted to organic chemistry, under such headings as Alicyclic Compounds, Alkaloids, Physical Organic Chemistry, Heterocyclic Compounds (One Heteroatom), and so on. Each abstract of a paper begins with a heading that gives (1) the abstract number;[15] (2) the title of the paper; (3) the authors' names as fully as given in the paper; (4) the authors' address; (5) the abbreviated name of the journal (see Table A.1);[16] (6) the year, volume, issue, and page numbers; and (7) the language of the paper. In earlier years, *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents begin with the abstract number, title, inventor and company (if any), patent number, patent class number, date patent issued, country of priority, patent application number, date patent applied for, and number of pages in the patent. The body of the abstract is a concise summary of the information in the paper. For many common journals, the author's summary (if there is one) is used in *CA* as it appears in the original paper, with perhaps some editing and additional information. Each issue of *CA* contains an author index, a patent index, and an index of keywords taken from the titles and the texts or contexts of the abstracts. The patent index lists all patents in order of number. The same compound or method is often patented in several countries. *Chemical Abstracts* abstracts only the first patent, but does list the patent numbers of the duplicated patents in the patent index along with all previous patent numbers that correspond to it. Before 1981 there were separate Patent Number Indexes and Patent Concordances (the latter began in 1963).

At the end of each section of *CA* there is a list of cross-references to related papers in other sections.

Chemical Abstracts is, of course, highly used for "current awareness"; it allows one to read, in one place, abstracts of virtually all new work in chemistry, though its large size puts a limit on the extent of this type of usefulness.[17] *Chemical Abstracts* is even more useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases to ascertain quickly where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes. Since 1962 there are two volumes published each year, and a separate index is issued for each volume. For each volume there is an index of subjects, authors, formulas, and patent numbers. Beginning in 1972 the subject index has been issued in two parts, a chemical substance index and a general subject index, which includes all entries that are not the names of single chemical substances. However, the indexes to each volume become essentially superseded as collective indexes are issued. The first collective indexes are 10-year (decennial) indexes, but the volume of information has made 5-year indexes necessary since 1956. Collective indexes so far published are shown in Table A.2. Thus a user of the indexes at the time of this writing would consult the collective indexes through 1995 and the semiannual indexes thereafter. The 14th collective index (covering 1997-2001) is scheduled to appear in 2002.

Beginning with the eighth collective index period, *CA* has published an *Index Guide.* This publication gives structural formulas and/or alternate names for thousands of compounds, as well as many other cross-references. It is designed to help the user efficiently and rapidly to find *CA* references to subjects of interest in the general subject, formula, and chemical substance indexes. Each collective index contains its own *Index Guide.* A new *Index Guide* is issued every 18 months. The *Index Guide* is necessary because the *CA* general subject index is a "controlled

TABLE A.2 *CA* Collective Indexes So Far Published

	Subject

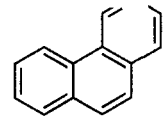
11	1982-1986	1982-1986	1982-1986	1982-1986	1982-1986
12	1987-1991	1987-1991	1987-1991	1987-1991	1987-1991
13	1992-1996	1992-1996	1992-1996	1992-1996	1992-1996
14					

index", meaning it restricts its entries only to certain terms. For example, anyone who looks for the term "refraction" in the general subject index will not find it. The *Index Guide* includes this term, and directs the reader to "Electromagnetic wave, refraction of", "Sound and ultrasound, refraction of", and other terms, all of which will be found in the general subject index. Similarly, the chemical substance index usually lists a compound only under one name the approved *CA* name. Trivial and other names will be found in the *Index Guide.* For example, the term "methyl carbonate" is not in the chemical substance index, but the *Index Guide* does have this term, and tells us to look for it in the chemical substance index under the headings "carbonic acid, esters, dimethyl ester" (for Me_2CO_3) and "carbonic acid, esters, monomethyl ester" (for $MeHCO_3$). Furthermore, the *Index Guide* gives terms related to the chosen term, helping users to broaden a search. For example, one who looks for "Atomic orbital" in the *Index Guide* will find the terms "Energy Level", "Molecular orbital", "Atomic integral", and "Exchange, quantum mechanical, integrals for", all of which are controlled index terms.

Along with each index (annual, semiannual, or collective) appears an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names. For example, someone wishing to determine whether any compounds containing this ring system



Benz(*h*)isoquinoline

are reported in the 1982–1986 collective index (even if he or she did not know the name) would locate, under the heading "3-ring systems" the listing **6, 6, 6** (since the compound has three rings of six members each), under which he or she would find the sublisting C_5N– C_6–C_6 (since one ring contains five carbons and a nitrogen while the others are all-carbon), under which is listed the name benz(*h*)isoquinoline, as well as the names of 30 other systems C_5N–C_6–C_6. A search of the chemical substance index under these names will give all references to these ring systems that have appeared in *CA* from 1982 to 1986.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page. These letters are for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years, superscript numbers (e.g., 4327^5) were used in a similar manner. In very early years, these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user must mentally divide the page into nine parts. Beginning with 1967, abstracts are individually numbered and column numbers are discarded. Therefore, beginning with 1967, index entries give abstract number rather than column number. The abstract numbers are followed by a letter that serves as a check character to prevent miscopying errors in computer handling. To use the *CA* general subject, chemical substance, and formula indexes

intelligently requires practice, and the student should become familiar with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides.*

In the *CA* formula indexes, formulas are listed in order of (1) number of carbon atoms; (2) number of hydrogen atoms; (3) other elements in alphabetic order. Thus, all C_3 compounds are listed before any C_4 compound; all C_5H_7 compounds before any C_5H_8 compound; $C_7H_{11}Br$ before C_7H_1,N; $C_9H_6N_4S$ before C_9H_6O, and so on. Deuterium and tritium are represented by D and T and treated alphabetically (e.g., C_2H_5DO after C_2H_5Cl and before C_2H_5F or C_2H_6).

Since 1965, *CA* has assigned a Registry Number to each unique chemical substance. This is a number of the form [766-51-8] that remains invariant, no matter what names are used in the literature. More than 10 million numbers have already been assigned and thousands are added each week. Registry Numbers are primarily for computer use. All numbers so far have been published with the *CA* preferred names in a multivolume "Registry Handbook".

For abstracts printed since 1967 (the eighth collective period and later), *CA* can be searched by computer online. For a discussion of online searching see pages. 1616, 1631.

Although *CA* and *Referativnyi Zhurnal, Khimya* are currently the only chemical abstracting publications that cover the entire field of chemistry, there were a number of earlier abstracting publications now defunct. The most important are *Chemisches Zentralblatt* and *British Abstracts.* These publications are still valuable because they began before *CA* and can therefore supply abstracts for papers that appeared before 1907. Furthermore, even for papers published after 1907, *Zentralblatt* and *British Abstracts* are often more detailed. *Zentralblatt* was published, under various names, from 1830 to 1969.[18] *British Abstracts* was a separate publication from 1926 to 1953, but earlier abstracts from this source are available in the *Journal of the Chemical Society* from 1871 to 1925.

Beilstein

This publication is so important to organic chemistry that it deserves a section by itself. Beilstein's "Handbuch der Organischen Chemie", usually referred to as *Beilstein,* lists all the known organic compounds reported in the literature during its period of coverage. For each compound are given: all names; the molecular formula; the structural formula; all methods of preparation (briefly, e.g., "by refluxing 1-butanol with NaBr and sulfuric acid"); physical constants such as melting point, refractive index, and so on; other physical properties; chemical properties including reactions; occurrence in nature (i.e., which species it was isolated from); biological properties, if any; derivatives with melting points; analytical data, and any other information that has been reported in the literature.[19] Equally important, for every piece of information, a reference is given to the original literature. Furthermore, the data in Beilstein have been critically evaluated. That is, all information is carefully researched and documented, and duplicate and erroneous results are eliminated.

Some compounds are discussed in two or three lines and others require several pages. The value of such a work should be obvious.

The first three editions of Beilstein are obsolete. The fourth edition *(vierte Auflage)* covers the literature from its beginnings through 1909. This edition, called *das Hauptwerk*, consists of 27 volumes. The compounds are arranged in order of a system too elaborate to discuss fully here.[20] The compounds are divided into three divisions which are further subdivided into "systems":

Division	Volumes	System Numbers
I. Acyclic Compounds	1-4	1-499
II. Carbocyclic Compounds	5-16	450-2359
III. Heterocyclic Compounds	17-27	2360-4720

Das Hauptwerk is still the basis of Beilstein and has not been superseded. The later literature is covered by supplements that have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement *(erstes Ergänzungswerk)* covers 1910-1919; the second supplement *(zweites Ergänzungwerk)* covers 1920-1929; the third supplement *(drittes Ergdnzungswerk)* covers 1930-1949; the fourth supplement *(viertes Ergdnzungswerk)* covers 1950-1959, and the fifth supplement covers 1960-1979. Like *das Hauptwerk*, each supplement contains 27 volumes,[21] except that supplements 3 and 4 are combined for vols. 17-27, so that for these volumes the combined third and fourth supplement covers the years 1930-1959. Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in vol. 3, system number 199 of *das Hauptwerk* will also be found in vol. 3, system number 199 of each supplement. To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound can be found in the earlier books. Thus, on page 554 of vol. 6 of the fourth supplement, under the listing phenetole are found the symbols (H 140; E I 80; E II 142; E III 545) indicating that earlier information on phenetole is given on page 140 of vol. 6 of *das Hauptwerk*, on page 80 of the first, page 142 of the second, and page 545 of the third supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all six series, location of a compound in any one series gives its location in the other five. If a compound is found, for example, in vol. 5 of *das Hauptwerk*, one has but to note the page number and scan vol. 5 of each supplement until that number appears in the top center of the page (the same number often covers several pages). Of course, many compounds are found in only one, two, three, four, or five of the series, since no work may have been published on that compound during a particular period covered. From *das Hauptwerk* to the fourth supplement, Beilstein is in German, though it is not difficult to read since most of the words are the names of compounds (a Beilstein German-English Dictionary, available free from the publisher, is in many libraries). For the fifth supplement

(covering 1960–1979), which is in English, publication of Division III began before the earlier divisions. At the time of this writing, vols. 17-22 (totaling 70 separate parts exclusive of index volumes) of this supplement have been published, as well as a combined index for volumes 17-19. This index covers only the fifth supplement. The subject portion of this index, which lists compound names only, gives these names in English.

Volumes 28 and 29 of Beilstein are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement and covers only *das Hauptwerk* and the first two supplements (though complete indexes covering *das Hauptwerk* and the first four supplements have been announced to appear in the next few years). For vol. 1, there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and the first four supplements.[22] Similar index volumes, covering all four supplements, have been issued for the other volumes, 2-27. Some of these are combined, (e.g., 2-3, 12-14, and 23-25). For English-speaking chemists (and probably for many German-speaking chemists), the formula indexes are more convenient. Of course (except for the fifth supplement indexes), one must still know some German, because most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers, (e.g., 1, 501). Roman numbers are used to indicate the supplements, (e.g., 26, 15, I 5, II 7). Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first four supplements. The Beilstein formula indexes are constructed the same way as the *CA* indexes (p. 1614).

There is also a fourth division of Beilstein (systems 4721-4877) that covers natural products of uncertain structure: rubbers, sugars, and so on. These are treated in vols. 30 and 31, which do not go beyond 1935 and which are covered in the collective indexes. These volumes will not be updated. All such compounds are now included in the regular Beilstein volumes.

Like *CA*, Beilstein is available online, including the useful search engine *CrossFire.*

Tables of Information

In addition to Beilstein, there are many other reference works in organic chemistry that are essentially compilations of data. These books are very useful and often save the research worker a great deal of time. In this section, we discuss some of the more important of such works.

1. The sixth edition of "Heilbron's Dictionary of Organic Compounds", J. Buckingham, Ed., 9 vols., Chapman and Hall, London, ***1996,*** contains brief listings of > 150,000 organic compounds, giving names, structural formulas, physical properties, and derivatives, with references. For many entries additional data concerning occurrence, biological activity, and toxicity hazard information are also given. The arrangement is alphabetical. The dictionary contains indexes of names, formulas, heteroatoms, and *CA*

Registry Numbers. Annual supplements, with cumulative indexes, have appeared since 1983. A similar work, devoted to organometallic compounds. is the 2nd edition of the "Dictionary of Organometallic Compounds"', 6 vols. in its 5th supplement, published by Chapman and Hall in ***1989.*** Another, "Dictionary of Steroids", 2 vols., 1991, is also published by Chapman and Hall.

2. A multivolume compendium of physical data is Landolt-Börnsteins's "Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik", 6th ed., Springer, Berlin, 1950–. There is also a "New Series", for which the volumes are given the English title "Numerical Data and Functional Relationships in Science and Technology", as well as the German title. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists, (e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data). Literature references are given for all data.
3. "The Handbook of Chemistry and Physics", CRC Press, Boca Raton, FL (called the "rubber handbook"), which is revised annually (81st ed., 2000-2001), is a valuable repository of data quickly found. For organic chemists the most important table is "Physical Constants of Organic Compounds", which lists names, formulas, color, solubilities, and physical properties of thousands of compounds. However, there are many other useful tables. A similar work is Lange's "Handbook of Chemistry", 13th ed., McGraw-Hill, New York, 1985. Another such handbook, but restricted to data of interest to organic chemists, is Dean, "Handbook of Organic Chemistry", McGraw-Hill, New York, 1987. This book also contains a long table of "Physical Constants of Organic Compounds", and has much other information including tables of thermodynamic properties, spectral peaks, pK_a values, bond distances, and dipole moments.
4. A list of most of the known natural compounds (e.g., terpenes, alkaloids, carbohydrates) to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in Devon and Scott, "Handbook of Naturally Occurring Compounds", 3 vols., Academic Press, New York, 1972.
5. Dreisbach, "Physical Properties of chemical Compounds", Advances in Chemistry Series nos. 15, 22, 29, American chemical Society, Washington, 1955-1961 lists many physical properties of more than 1000 organic compounds.
6. Physical properties of thousands of organometallic compounds, with references, are collected in five large compendia: the "Dictionary of Organometallic Compounds", mentioned under item 1, above; Dub, "Organometallic Compounds", 2nd ed., 3 vols. with supplements and index, Springer, New York, 1966–1975; Hagihara, Kumada, and Okawara, "Handbook of Organometallic Compounds", W. A. Benjamin, New York, 1968; and Kaufman, "Handbook of Organometallic Compounds", Van

Nostrand, Princeton, NJ, 1961; "Comprehensive Organometallic Chemistry II", 14 vols., Pergamon, 1995.

7. The "Merck Index", 12th ed., Merck and Company, Rahway, NJ, ***1996*** is a good source of information about chemicals of medicinal importance. Many drugs are given three types of name: chemical *name* (which is the name an organic chemist would give it; of course, there may well be more than one); *generic name*, which must be placed on all containers of the drug; and *trade names*, which are different for each company that markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine is chlorcyclazine. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazyl, and Alergicide. The Merck Index is especially valuable because it gives all known names of all three types for each compound and the names are cross-indexed. Also given, for each compound, are the structural formula, *CA* preferred name and Registry Number, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. There are indexes of formulas and Registry Numbers, and miscellaneous tables. The 10th edition of the Merck Index (1983) also includes a lengthy list of organic name reactions, with references. The 11th edition omits this list, but it is restored in the 12th edition.
8. There are two publications that list properties of azeotropic mixtures. Timmermans, "The Physicochemical Constants of Binary Systems in Concentrated Solutions", 4 vols., Interscience, New York, 1959-1960, is by far the more comprehensive. The other is "Azeotropic Data", 2 vols., Advances in Chemistry Series no. 6 and no. 35, American chemical Society, Washington, 1952, 1962.
9. Thousands of dipole moments, with references, are collected in McClellan, "Tables of Experimental Dipole Moments", vol. 1, W.H. Freeman, San Francisco, CA, 1963; vol. 2, Rahara Enterprises, El Cerrita, CA, 1974.
10. "Tables of Interatomic Distances and Configurations in Molecules and Ions", London Chemical Society Special publication no. 11, 1958, and its supplement, Special publication no. 18, 1965, include bond distances and angles for hundreds of compounds, along with references.
11. The "Ring Systems Handbook", published in 1988 by the Chemical Abstracts Service, provides the names and formulas of ring and cage systems that have been published in *CA*. The ring systems are listed under a system essentially the same as that used for the *CA* index of ring systems (p. 1613). Each entry gives the *CA* index name and Registry Number for that ring system. In many cases, a *CA* reference is also given. There is a separate Formula Index (for the parent ring systems) and a Ring Name Index. Cumulative supplements are issued twice a year. The "Ring Systems Handbook" supersedes earlier publications called "The Parent Compound Handbook" and "The Ring Index".
12. The Sadtler Research Laboratories publish large collections of IR, UV, NMR, and other spectra, in loose-leaf form. Indexes are available.

13. Infrared, UV, NMR, Raman, and mass spectral data, as well as melting point, boiling point, solubility, density, and other data for > 30,000 organic compounds are collected in the "CRC Handbook of Data on Organic Compounds", 2nd ed., 9 vols., CRC Press, Boca Raton, FL, 1988, edited by Weast and Grasselli. It differs from the Sadtler collection in that the data are given in tabular form (lists of peaks) rather than reproduction of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear at one place. References are given to the Sadtler and other collections of spectra. Volumes 7-9 contain indexes of spectral peaks for IR, UV, NM, NMR, ^{13}C NMR, mass, and Raman spectra, as well as indexes of other names, molecular formulas, molecular weights, and physical constants. Annual updates began appearing in 1990 (the first one is called volume 10).
14. The "Aldrich Library of Infrared Spectra", 3rd ed., Aldrich chemical Company, Milwaukee, WI, 1981, by Pouchert contains more than 12,000 IR spectra so arranged that the user can readily see the change that takes place in a given spectrum when a slight change is made in the structure of a molecule. The same company also publishes the "Aldrich Library of FT–IR Spectra" and the "Aldrich Library of NMR Spectra", both also by Pouchert. A similar volume, which has ir and Raman spectra of about 1000 compounds, is "Raman/Infrared Atlas of Organic Compounds", 2nd ed., VCH, New York, 1989, by Schrader.
15. An extensive list of visible and UV peaks is given in "Organic Electronic Spectral Data", Wiley, New York. Twenty-six volumes have appeared so far, covering the literature through 1984.
16. A collection of 500 ^{13}C NMR spectra is found in Johnson and Jankowski, "Carbon-13 NMR Spectra", Wiley, New York, 1972.

Reviews

A review article is an intensive survey of a rather narrow field; for example, the titles of some recent reviews are "Desulfonation Reactions: Recent Developments",[23] "Pyrrolizidine and Indolizidine Syntheses Involving 1,3-Dipolar Cycloaddtion",[24] and "From Corrin Chemistry to Asymmetry Catalysis—A Personal Account."[25] A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though most are not exclusively devoted to organic chemistry) are shown in Table A.3. Some of the journals listed in Table A.1, for example, the *Bull Soc. Chim. Fr.* and *J. Organomet. Chem.* also publish occasional review articles.

There are several open-ended serial publications that are similar in content to the review journals but are published irregularly (seldom more often than once a year) and are hardbound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; some specialize further. The coverage is indicated by

TABLE A.3 Review Journals, With Year of Founding and Issues per Year as of 1998

Accounts of Chemical Research (1968)	12
Aldrichimica Acta (1968)	4
Angewandte **Chem**ie (1888)	12
and its English Translation:	
Angewandte Chemie, International Edition in English (1962)	12

[b] See Ref. 27.

the titles. Table A.4 shows some of the more important such publications, with *CA* abbreviations.

There are several publications that provide listings of review articles in organic chemistry. The most important is the *J. Org. Chem.*, which began to list review articles in 1978 (the first list is at *J. Org. Chem., 43,* 3085), suspended the listings in 1985, and resumed them in 1990 (at *J. Org. Chem., 55,* 398). These lists, which appear about four times a year, give the titles and reference sources of virtually all review articles in the field of organic chemistry that have appeared in the preceding three months, including those in the review journals and serials mentioned above, as well as those in monographs and treatises. There is also a listing of new monographs on a single subject. Each list includes a subject index.

Another publication is the "Index of Reviews in Organic Chemistry", complied by Lewis, Chemical Society, London, a classified listing of review articles. The first volume, published in 1971, lists reviews from $\sim$ 1960 (in some cases much earlier) to $\sim$1970 in alphabetical order of topic. Thus four reviews are listed under "Knoevenagel condensation", five under "Inclusion compounds", and one under "Vinyl ketones." There is no index. A second volume (1977) covers the literature to 1976. Annual or biannual supplements appeared from 1979 until the publication was terminated in 1985. Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton[28] and by Bruce.[29] A similar list for heterocyclic chemistry is found in articles by Katritzky and others.[30] See also the discussion of the *Index of Scientific Reviews,* page 1638.

Topics in Physical Organometallic Chemistry
Topics in Stereochemistry

Annual Reviews

The review articles discussed in the previous section are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication that covers a broad area but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication still publishing is *Annual Reports on the Progress of Chemistry*, published by the Royal Society of Chemistry (formerly the chemical Society), which began in 1905 and which covers the whole field of chemistry. Since 1967 it has been divided into sections. Organic chemistry is found in Section B.
2. Because the number of papers in chemistry has become so large, the Royal Society of Chemistry publishes annual review type volumes of smaller scope,

called *Specialist Periodical Reports.* Among those of interest to organic chemists are "Carbohydrate Chemistry" (vol. 22 covers 1988); "Photochemistry" (vol. 21 covers 1988-1989); and "General and Synthetic Methods", (vol. 12 covers 1987).

3. "Organic Reaction Mechanisms", published by Wiley, New York, is an annual survey that covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.
4. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, "Synthetic Methods of Organic Chemistry", S. Karger Verlag, Basel, is an annual compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond closings and bond breakings. Equations, brief procedures, yields, and literature references are given. Volume 44 was issued in 1990. Volumes 3 and 4 are available only in German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is "Annual Reports in Organic Synthesis," Academic Press, New York, which has covered the literature of each year since 1970. Equations are listed with yields and references according to a fairly simple system.
5. The *Journal of Organometallic Chemistry* several times a year publishes annual surveys arranged according to metallic element. For example, vol. 404, published in February 1991, contains annual surveys for 1989 of organic compounds containing Sb, Bi, and Fe, and the use of transition metals in organic synthesis, and surveys for 1988 covering B, Ru, and Os.

Awareness Services

Besides the annual reviews and the title and abstract services previously mentioned, there exist a number of publications designed to keep readers aware of new developments in organic chemistry or in specific areas of it.

1. *Chemtracts: Organic Chemistry* is a bimonthly Periodical, begun in 1988, that prints abstracts of certain recently published papers (those that the editors consider most important), with commentaries on these papers by distinguished organic chemists. Each issue deals with about 20 papers, and also includes a review article.
2. The Institute for Scientific Information (ISI), besides publishing *Current Contents* (p. 1611) and the *Science Citation Index* (p. 1637), also publishes *Index Chemicus* (formerly called *Current Abstracts of Chemistry and Index Chemicus).* This publication, begun in 1960 and appearing weekly, is devoted to printing structural formulas of all new compounds appearing in more than 100 journals, along with equations to show how they were synthesized and an author's summary of the work. Each issue contains five indexes: author,

journal, biological activity, labeled compounds, and unisolated intermediates. These indexes are cumulated annually.

3. Theilheimer and the "Annual Reports on Organic Synthesis", mentioned in the previous section, list new synthetic methods once a year. There are several publications that do this monthly. Among these are *Current Chemical Reactions* (begun in 1979 and published by ISI), *Journal of Synthetic Methods* (begun in 1975 and published by Derwent publications), and *Methods in Organic Synthesis,* begun in 1984 and published by the Royal Society of Chemistry. *Methods in Organic Synthesis* also lists books and review articles pertaining to organic synthesis.
4. *Natural Product Updates,* a monthly publication begun in 1987 and published by the Royal Society of Chemistry, lists recent results in the chemistry of natural products, along with structural formulas. It covers new compounds, structure determinations, new properties and total syntheses, among other topics.

General Treatises

There are a number of large-scale multivolume treatises that cover the whole field of organic chemistry or large areas of it.

1. "Rodd's Chemistry of Carbon Compounds", edited by Coffey, Elsevier, Amsterdam, is a treatise consisting of five main volumes, each of which contains several parts. Publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to many of the volumes have appeared. An earlier edition, called "Chemistry of Carbon Compounds", edited by Rodd, was published in 10 parts from 1951 to 1962.
2. Houben-Weyl's "Methoden der Organischen Chemie'', Georg Thieme Verlag, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 20 volumes, most of them in several parts, is edited by E. Muller. The series includes supplementary volumes. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the synthesis of specific types of compounds, (e.g., hydrocarbons, oxygen compounds, and and nitrogen compounds). Beginning in 1990 parts of the series have appeared in English.
3. "Comprehensive Organic Chemistry", Pergamon, Elmsford, NY, 1979, is a six-volume treatise on the synthesis and reactions of organic compounds. The first three volumes cover the various functional groups, vol. 4, heterocyclic compounds, and vol. 5, biological compounds such as proteins, carbohydrates, and lipids. Probably the most useful volume is vol. 6, which contains formula, subject, and author indexes, as well as indexes of reactions and

reagents. The last two of these not only refer to pages within the treatise, but directly give references to review articles and original papers. For example, on page 1129, under "Chromic acid–sulfuric acid (Jones reagent), oxidation, alcohols", are listed 13 references to original papers. Several similar treatises, including the nine-volume "Comprehensive Organometallic Chemistry" (1982), the eight-volume "Comprehensive Heterocyclic Chemistry" (1984), and the six-volume "Comprehensive Medicinal Chemistry" (1989) are also published by Pergamon. The indexes to these works also include references.

4. A major treatise devoted to experimental methods of chemistry is "Techniques of Chemistry", edited first by Weissberger, and then by Saunders, Wiley, New York. This publication, which began in 1970, so far consists of 21 volumes, most of them in several parts, covering such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. "Techniques of Chemistry" is a successor to an earlier series, called "Techniques of Organic Chemistry", which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969.
5. "Comprehensive Chemical Kinetics", edited by Bamford and Tipper, 1969—, Elsevier, Amsterdam, is a multivolume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.
6. Three multivolume treatises that cover specific areas are Elderfield, "Heterocyclic Compounds", Wiley, New York, 1950- ; Manske and Holmes, "The Alkaloids", Academic Press, New York, 1950- ; and Simonson, Owen, Barton, and Ross, "The Terpenes", Cambridge University Press, London, 1947-1957.
7. "Encyclopedia of Reagents for Organic Synthesis", edited by Paquette, Wiley, New York, was published in 1995. It is an 8 volume, alphabetic listing of reagents used in organic chemistry with descriptions of the preparation, use and chemistry, with references. Each reagent was researched by organic chemists active in research, who contributed to the total publication.
8. "Comprehensive Organic Synthesis", edited by Trost and Fleming, Pergamon, was published in 1991. It is a nine volume compilation.
9. "Comprehensive Organic Functional Group Transformations", edited by Katritzky, Meth-Cohn, and Rees, Pergamon, was published in 1995. It is a seven volume compilation.

Monographs and Treatises on Specific Areas

Organic chemistry is blessed with a large number of books devoted to a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some of the books are by a single author, and others have chapters by different authors but all are carefully planned to cover a specific area. Many of these books have been referred to in

footnotes in appropriate places in this book. There have been several series of monographs, one of which is worth special mention: "The Chemistry of Functional Groups", under the general editorship of Patai, published by Wiley, New York. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. Volumes covering more than 20 functional groups have appeared so far, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, quinones, and so on.

Textbooks

There are many excellent textbooks in the field of organic chemistry. We restrict ourselves to listing only a few of those published, mostly since 1985. Some of these are first-year texts and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.); some cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are not only good textbooks but valuable reference books for graduate students and practicing chemists.

Carey, "Organic Chemistry", 3rd ed., McGraw-Hill, New York, 1996.

Carey and Sundberg, "Advanced Organic Chemistry", 2 vols., Plenum, New York, 3rd. ed., 1990.

Carruthers, "Some Modern Methods of Organic Synthesis", 3rd ed., Cambridge University Press, Cambridge, 1986.

Ege, "Organic Chemistry", 4th ed., D.C. Houghton Mifflin, Boston 1999.

Fessenden and Fessenden, "Organic Chemistry", 6th ed., Brooks/Cole, Monterey, CA, 1998.

Fox and Whitesell, "Organic Chemistry", 2nd ed, Jones and Bartlett, Sudbury, MA, 1997.

Other Books

In this section, we mention several books that do not fit conveniently into the previous categories. All but the last have to do with laboratory synthesis.

1. *Organic Syntheses*, published by Wiley, New York is a collection of procedures for the preparation of specific compounds. The thin annual volumes have appeared each year since 1921. For the first 59 volumes, the procedures for each 10- (or 9-) year period are collected in cumulative volumes. Beginning with vol. 60, the cumulative volumes cover five-year periods. The cumulative volumes published so far are

Annual Volumes	Collective Volumes
1-9	I
10-19	II
20-29	HI
30-39	IV
40-49	V
50-59	VI
60-64	VII
65-69	VIII
70-74	IX

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested.* Each preparation is carried out first by its author and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most

procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in Beilstein and in *CA.* In order to locate a given reaction in *Organic Syntheses,* the reader may use the OS references given in the present volume (through OS 69); the indexes in *Organic Syntheses* itself; Shriner and Shriner, *"Organic Syntheses* Collective Volumes I, II, III, IV, V Cumulative Indexes", Wiley, New York, 1976, or Sugasawa and Nakai; "Reaction Index of *Organic Syntheses",* Wiley, New York, 1967 (through OS 45). Another book classifies virtually all the reactions in *Organic Syntheses* (collective vols. I–VII and annual vols. 65-68) into 11 categories: annulation, rearrangement, oxidation, reduction, addition, elimination, substitution, C–C bond formation, cleavage, protection/deprotection, and miscellaneous. This is *"Organic Syntheses:* Reaction Guide", by Liotta and Volmer, published by Wiley, New York, in 1991. Some of the categories are subdivided further, and some reactions are listed in more than one category. What is given under each entry are the equation and the volume and page reference to *Organic Syntheses.*

2. Volume 1 of "Reagents for Organic Synthesis", by Fieser and Fieser, Wiley, New York, 1967, is a 1457-page volume that discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. Eighteen additional volumes have so far been published, which continue the format of vol. 1 and add more recent material. A cumulative index for vols. 1-12, by Smith and Fieser, was published in 1990. The series has recently been resumed, after the death of Mary Fieser, by L. Ho.

3. "Comprehensive Organic Transformations", by Larock, VCH, New York, 1989, has been frequently referred to in footnotes in Part 2 of this book. This compendium is devoted to listings of methods for the conversion of one functional group into another, and covers the literature through 1987. It is divided into nine sections covering the preparation of alkanes and arenes, alkenes, alkynes, halides, amines, ethers, alcohols and phenols, aldehydes and ketones, and nitriles, carboxylic acids and derivatives. Within each section are given many methods for synthesizing the given type of compound, arranged in a logical system. A schematic equation is given for each method, and then a list of references (without author names, to save space) for locating examples of the use of that method. When different reagents are used for the same functional group transformation, the particular reagent is shown for each reference. There is a 164-page index of group transformations. The 2nd edition has only recently been published and is *not* referenced in this edition, and a CD-ROM version is now available.

4. "Survey of Organic Synthesis", by Buehler and Pearson, Wiley, New York, 2 vols., 1970, 1977, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group (e.g., ketones, acyl halides, and amines). Each

reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.

5. A similar publication is Sandier and Karo, "Organic Functional Group Preparations", 2nd ed., 3 vols., Academic Press, New York, 1983-1989. This publication covers more functional groups than Buehler and Pearson.
6. "Compendium of Organic Synthetic Methods", Wiley, New York, contains equations describing the preparation of thousands of monofunctional and difunctional compounds with references. Nine volumes have been published so far (1971 and 1974, edited by Harrison and Harrison; 1977, edited by Hegedus and Wade; 1980 and 1984, edited by Wade; 1988, 1992, 1995, and 2000 edited by Smith). Volume 10 will appear in 2000-2001.
7. "The Vocabulary of Organic Chemistry", by Orchin, Kaplan, Macomber, Wilson, and Zimmer, Wiley, New York, 1980, presents definitions of more than 1000 terms used in many branches of organic chemistry, including stereochemistry, thermodynamics, wave mechanics, natural products, and fossil fuels. There are also lists of classes of organic compounds, types of mechanism, and name reactions (with mechanisms). The arrangement is topical rather than alphabetical, but there is a good index. "Compendium of Chemical Terminology", by Gold, Loening, McNaught, and Sehmi (the Gold book), published by Blackwell Scientific publications, Oxford, in 1987, is an official IUPAC list of definitions of terms in several areas of chemistry, including organic.

LITERATURE SEARCHING

Until recently searching the chemical literature meant looking only at printed materials (some of which might be on microfilm or microfiche). Now, however, much of the literature can be searched online, including some of the most important. Whether the search is online or uses only the printed material, there are two basic types of search, (1) searches for information about one or more specific compounds or classes of compounds, and (2) other types of searches. First, we will discuss searches using only printed materials, and then online searching.[32]

Literature Searching Using Printed Materials

Searching for Specific Compounds. Organic chemists often need to know if a compound has ever been prepared and if so, how, and/or they may be seeking a melting point, an IR spectrum, or some other property. Someone who wants all the information that has ever been published on any compound begins by consulting the formula indexes in Beilstein (p. 1614). At this time there are two ways to do this. (1) The formula index to the second supplement (vol. 29, see p. 1614) will quickly show whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. Use of the page heading method described on p. 1614 will then show the locations, if any, in the

third and later supplements. (2) If one has an idea which volume of Beilstein the compound is in (and the tables of contents at the front of the volumes may help), one may search the cumulative index for that volume. If not sure, one may consult several indexes. One of these two procedures will locate all compounds mentioned in the literature through 1959. If the compound is heterocyclic, it may be in the fifth supplement. If it is in vols. 17-19 (or in a later volume whose index has been published), the corresponding indexes may be consulted. If not, the page heading method will find it, if it was reported before 1960.[31] There is a way by which all of the above can be avoided. A computer program, called SANDRA (available from the Beilstein publisher), allows the user to find the Beilstein location by using a mouse to draw the structural formula of the compound sought. At this point the investigator will know (1) all information published through 1959 or 1979,[32] or (2) that the compound is not mentioned in the literature through 1959 or 1979.[32] In some cases, scrutiny of Beilstein will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search past 1959 (or 1979), the chemist next turns to the collective formula indexes of *Chemical Abstracts:* 1957-1961; 1962-1966; 1967-1971; 1972-1976; 1977-1981; 1982-1986; 1987-1991; 1992-1996 and such later collective indexes as have appeared; and the semiannual indexes thereafter. If a given formula index contains only a few references to the compound in question, the pages or abstract numbers will be given directly in the formula index. However, if there are many references, the reader will be directed to see the chemical substance index or (before 1972) the subject index for the same period; and here the number of page or abstract numbers may be very large indeed. Fortunately, numerous subheadings are given, and these often help the user to narrow the search to the more promising entries. Nevertheless, one will undoubtedly turn to many abstracts that do not prove to be helpful. In many cases, the information in the abstracts will be sufficient. If not, the original references must be consulted. In some cases (the index entry is marked by an asterisk or a double asterisk) the compound is not mentioned in the abstract, though it is in the original paper or patent. Incidentally, all entries in the *CA* indexes that refer to patents are prefixed by the letter P. Since 1967, the prefixes B and R have also been used, to signify books and reviews, respectively.

By the procedure outlined above, all information regarding a specific compound that has been published up to about a year before the search can be found by a procedure that is always straightforward and that in many cases is rapid (if the compound has been reported only a few times). Equally important, if the compound has not been reported, the investigator will know that, too. It should be pointed out that for common compounds, such as benzene, ether, acetone, and so on, trivial mentions in the literature are not indexed (so they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluant in a common procedure.

The best way to learn if a compound is mentioned in the literature after the period covered by the latest semiannual formula index of *CA* is to use the online services (p.

1631). However, if one lacks access to these, one may consult *Chemical Titles* and the keyword index (p. 1611) at the end of each issue of *CA*. In these cases, of course, it is necessary to know what name might be used for the compound. The name is not necessary for *Index Chemicus* (p. 1622); one consults the formula indexes. However, these methods are far from complete. *Index Chemicus* lists primarily new compounds, those which would not have been found in the earlier search. As for chemical *Titles*, the compound can be found only if it is mentioned in the title. The keyword indexes in *CA* are more complete, being based on internal subject matter as well as title, but they are by no means exhaustive. Furthermore, all three of these publications lag some distance behind the original journals. To locate all references to a compound after the period covered by the latest semiannual formula index of *CA*, it is necessary to use *CAS*-online.

The complete procedure described above may not be necessary in all cases. Often all the information one needs about a compound will be found in one of the handbooks (p. 1617), in the "Dictionary of Organic Compounds" (p. 1617), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

Other Searches.[33] There is no definite procedure for making other literature searches using only printed materials. Any chemist who wishes to learn all that is known about the mechanism of the reaction between aldehydes and HCN, or which compounds of the general formula Ar_3CR have been prepared, or which are the best catalysts for Friedel-Crafts acylation of naphthalene derivatives with anhydrides, or where the group $-C(NH_2)=N-$ absorbs in the IR, is dependent on his or her ingenuity and knowledge of the literature. If a specific piece of information is needed, it may be possible to find it in one of the compendia mentioned previously. If the topic is more general, the best procedure is often to begin by consulting one or more monographs, treatises, or textbooks that will give general background information and often provide references to review articles and original papers. In many cases this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, where the ingenuity of the investigator is most required, for now it must be decided which words to look under. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under "aldehydes", or "hydrogen cyanide", or even under "acetaldehyde" or "benzaldehyde," and so on., but then the search is likely to prove long. A better choice in this case would be "cyanohydrin", since these are the normal products and references there would be fewer. It would be a waste of time to look under "mechanism". In any case, many of the abstracts would not prove helpful. Literature searching of this kind is necessarily a wasteful process. Of course, the searcher would not consult the *CA* annual indexes but only the collective indexes as far as they go and the semiannual indexes thereafter. If it is necessary to search before 1907 (and even before 1920, since *CA* was not very complete from 1907 to $\sim$1920), recourse may be made to *Chemisches Zentralblatt* (p. 1614) and the abstracts in the *Journal of the Chemical Society* (p. 1614).

Literature Searching Online[32]

Online searching means using a computer terminal to search a *database.* Although databases in chemistry are available from several organizations, by far the most important such organization is STN International (The Scientific & Technical Information Network), which is available in many countries. The STN has dozens of databases, including many that cover chemistry and chemical engineering. To access these databases a chemistry department, a library, or an individual subscribes to STN (for a nominal fee), and receives code numbers that will permit access to the system. Then all one needs is a computer and a modem. The STN charges for each use, depending on which databases are used, for how long, and what kind of information is requested. One of the nice features of STN is that the same command language is used for all databases, so when one has mastered the language for one database, one can use it for all the others. In this section, we will discuss literature searching using *CAS* online, which is one of the databases available from STN. One thing that must be remembered is that *CAS* online is complete only from 1967 to the present,[34] so that searches for earlier abstracts must use the printed volumes. However, for the period since 1967, not only is online searching a great deal faster than searching the printed *CA,* but, as we shall see, one can do kinds of searches online that are simply not possible using only the printed volumes. Furthermore, the online files are updated every 2 weeks, so that one will find all the abstracts online well past the appearance of the latest semiannual indexes, often even before the library has received the latest weekly printed issue of *CA. Chemical Abstracts Service* online is extremely flexible; one can search in a great many ways. It is beyond the scope of this book to discuss the system in detail[35] *(CA* conducts workshops on its use), but even with the few commands we will give here, a user can often find all that he or she is looking for. *Chemical Abstracts Service* online has two major files, *the CA File* and *the Registry File.*[36] These are so different that we discuss them separately.

THE CA FILE

This file is accessed with the command FILE *CA.* Once in the file, the user uses the command SEARCH (or SEA or S)[37] to look for references to specific terms. For example, one may type SEA SEMIPINACOL. On the screen will appear something like

L1 4 SEMIPINACOL

The L1 means that this is line one. Future answers from the system will number the lines in consecutive order. The 4 means that the system has four abstracts that contain the word semipinacol. The word may be in the title, an index entry, or a keyword. The search term may be the name of a compound, which means that individual compounds can be searched for in this way. If the name used is the *CA* indexing name, all the abstracts mentioning that compound will be retrieved.

However, common names or other names can also be searched (e.g., catechol), and if they are mentioned in the title of the paper, or, for example as a keyword, those abstracts will be retrieved.

Compounds can also be searched for by using the Registry Number, for example.,

SEARCH 126786-44-3

Let us return to the example of semipinacol. The system told us there were four abstracts for this term. We may now see these abstracts by using the display command (DISPLAY or DIS or D), for example,

D L1 1 BIB ABS

The L1 means we are asking the system to display material pertaining to semipinacol, which is on line L1. If we fail to insert this information, the system will display items pertaining to the last L number shown.

The 1 means we are asking for information on the first of the four papers. The papers are listed in reverse chronological order, meaning paper 1 will be the latest of the four. Similarly, we can ask to see the information on any of the others.

The BIB ABS means we are asking for bibliographic data (abstract number, title of paper, authors' names, journal, year, etc.) and for a display of the full abstract.[38] There are other choices. Instead of BIB ABS we could have typed *CAN*, which would give us the abstract number only (we might then choose to find the other information in the printed *CA).* Or, we could have typed IND, which would give us the abstract number and the index terms for this paper, or ALL, which would give everything we get from BIB ABS plus the index terms. In all, there are 9 or 10 ways to ask for display material. Our choice will depend on how much we need to know, and on the cost, since the more information requested, the higher the cost.

As so far described, online searching is faster then searching the printed *CA,* but gives us essentially the same information. The scope of the online method is much greater than that, for it allows us to combine words, in a number of ways. One such way is by the use of the terms AND, NOT, and OR. If we search AMBIDENT AND NUCLEOPHILE, we will get something like this

332 AMBIDENT
3275 NUCLEOPHILE
L2 42 AMBIDENT AND NUCLEOPHILE

This means there are 42 entries that have the words AMBIDENT and NUCLEOPHILE somewhere in them; in the titles, keywords, or index entries. We can now, if we wish, display any or all of them. But a particular entry might have these two words in unrelated contexts, for example, it might be a paper about ambident electrophiles, but which also has NUCLEOPHILE as an index term. We would presumably get fewer papers, but with a higher percentage of relevant ones, if we could ask for AMBIDENT NUCLEOPHILE, and in fact, the system does allow

this. If we type S AMBIDENT(W)NUCLEOPHILE, we will get only those papers in which the term NUCLEOPHILE directly follows AMBIDENT, with no words in between.[39] This is called proximity searching, and there are other, similar commands. For example, the use of (4A) instead of (W) will give all instances in which the two words appear 4 or fewer words apart, in either order.

Another important option is a truncation symbol. If we ask for NUCLEOPHILE we will find all entries that contain the term nucleophile, but not those that contain a different form of this term (e.g., nucleophilic). We can take care of this by using NUCLEOPHIL? as a search term instead of NUCLEOPHILE. This will retrieve all terms that start with the letters NUCLEOPHIL, no matter what other letters follow, thus retrieving nucleophilic, nucleophilicity, nucleophiles, and so on, as well as nucleophile. The question mark is one of several truncation symbols, each of which serves a different function.

The words AND, NOT, and OR are called *Boolean operators*. They may be combined in many ways, for example,

S ORTHO AND EFFECT AND HAMMETT
S (carbon(W)DIOXIDE OR carbon(W)DISULFIDE) AND CATALY? NOT ACID
S HYDANTOIN AND (METHYL OR ETHYL) NOT (VINYL? OR PHENYL)

A particular search command can contain dozens of such terms. Obviously, if one is careful about choosing the proper search terms, one can focus in on just the relevant papers, and leave out those that will not be useful. However, there will often be far more papers than can conveniently be handled, and there are other ways to limit searches. One such way is by using a narrow field. For example, a synthetic chemist may wish to find references in which a given compound is synthesized, but find, when he or she searches for that compound, that most of the references concern biological or medicinal uses of the compound. By using the command

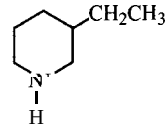
SEA 3489-26-7/ORG

the search will retrieve only those papers for the compound of Registry Number 3489-26-7 that have been abstracted in the organic (ORG) sections of *CA* (Sections 21-34), and will not retrieve papers from the biochemical sections, which are more likely to stress biological or medicinal uses. There are many other ways to limit searches. It is possible to search only for papers in a single section of *CA*, only those that appeared in a given year or range of years, only those in which the search term appears in the title of the paper, only those by a given author, and so on.

Besides subject terms, the *CA* File also contains bibliographical information, such as author names, location of the laboratory in which the work was done, language of the paper, and so on, and these can be searched. For example, S ROBERTS, J?/AU will find all papers published by any authors named Roberts whose first name begins with J. These terms can be combined with subject terms in Boolean searches.

THE REGISTRY FILE

The Registry File is entered with the command FILE REGISTRY. This can be done at any time, and it is possible to go back and forth between the *CA* and Registry Files at will. The Registry File uses the same commands (including Boolean) as the *CA* File, but instead of displaying abstracts and bibliographical information, it displays information about compounds. Its most useful feature is that it allows the user to build a structure, and then gives information about compounds that possess that structure, even if the structure is only part of a larger structure (see below).



3-Ethylpiperidine

The procedure for building a structure can be long and complex, if the structure is large and complex, but the commands are simple. We will illustrate by building the structure for 3-ethylpiperidine, which uses the most important commands. We begin with the command STRUCTURE. The system will ask if we wish to build on a structure previously used. If we say no, we will then get the prompt

ENTER (DIS), GRA, NOD, BON OR ?:

GRA is used for putting in chains or rings. We enter GRA R6, DIS (the DIS must be typed if the structure is to be displayed), and get the structure 1 shown in Figure A. 1.[40] The R6 specifies a six-membered ring. If we had simply entered 6 we would

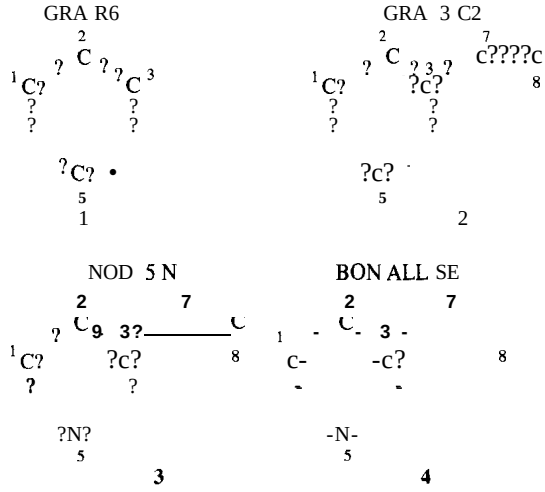


FIGURE A.1 Steps in building the structure of 3-ethylpiperidine in the Registry File. Above each structure is the command that gave that structure.

have created a six-atom chain. The six numbers shown are purely arbitrary and have no connection with the way the positions are actually numbered in any nomenclature scheme. Immediately after this structure is displayed, the same prompt reappears, as it does after every structure. We wish to introduce a two-atom side chain (the ethyl group), so we enter GRA 3 C2, DIS, and get structure 2 in Figure A.1. The C2 indicates a two-atom chain, and the 3 means that we want it attached to atom 3 (in this case the atom number is completely arbitrary, since attachment to any atom would give an equivalent result). Note that the system has numbered the new atoms 7 and 8. We will not be introducing any more atoms into our structure, but if we were they would be numbered consecutively, in the order in which they were introduced. We have all the atoms we need (we do not indicate the hydrogens because the system assumes that all nonspecified valences are connected to hydrogen, unless we tell it otherwise), but we still have not told the system about the nitrogen. Although the system uses C to specify all atoms, they will only remain carbon atoms until we instruct the system differently. To get 3-ethylpiperidine, the atom in the 5 position must be nitrogen. A C can be changed to another element by using NOD (for node), so we now type NOD 5 N, DIS. This changes C-5 to N-5, giving all the atoms in their final positions (3 in Fig. A.1). However, the structure is still not complete because the bonds have not been specified. By using the BON command we can make any bond single, double, or triple, and can even indicate aromaticity or other resonance. In this case we want all the bonds to be single bonds, so we type BON ALL SE, DIS (SE is used for single bonds), and get our final structure 4 in Figure A.1.

At this point we type END, and get

L1 STRUCTURE CREATED

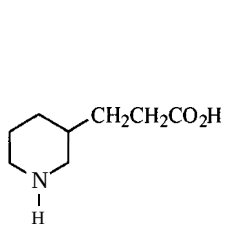
The structure is now ready to be searched. At the command SEARCH L1, the system will give the prompts

ENTER TYPE OF SEARCH (SSS), CSS, FAMILY, OR EXACT:
ENTER SCOPE OF SEARCH (SAMPLE), FULL, RANGE, OR SUBSET:

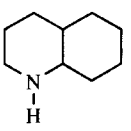
The system asks for the desired scope, because a full search (of the entire Registry File of > 10 million substances) may cost a lot of money and may not be worth it if the desired answers can be obtained from a more limited search.

As shown by the first prompt there are four types of search, of which we will discuss two: exact and substructure (SSS). In an exact search, only information regarding exactly the structure given will be retrieved, but even so there may well be several answers, because *CA* treats stereoisomers and isotopically substituted compounds as separate answers. At the conclusion of the search the system gives the number of answers, (e.g., 4). We may now look at the four answers by using the display command. As in the *CA* File, there is a choice of display formats, but if we choose SUB we will get (1) the Registry Number, (2) the approved *CA* index name, (3) other names that have appeared in *CA* for that compound, (4) a structural formula, and (5) the number of *CA* references since 1967, along with a notation as to

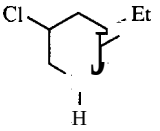
whether the compound is found in the CAOLD File. By using other display formats, we can also obtain the bibliographic information and abstracts for the latest 10 references. If there are more than 10 *CA* references, we can of course switch to the *CA* File, and use the Registry Number to search that file completely. If the exact structure search yields no answers, we know that no references to it have appeared in *CA* since 1967.



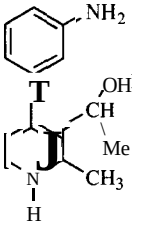
5



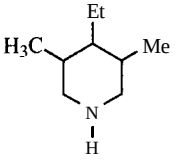
6



7



8



9

Although an exact search can be useful, in most cases it does not give any more information than can be obtained from the printed *CA.* Substructure searches (SSS) are far more important, because there is no other way to get this information. If we do a substructure search on 4 in Figure A. 1, we not only get all the answers we would get in an exact search, but all substances that contain, anywhere within their structure, the arrangement of atoms and bonds shown in 4. For example, 5, 6, 7, and 8 would all be retrieved in this search, but 9 would not be. The SSS searches typically retrieve from tens to hundreds of times as many answers as exact searches of the same structure. Furthermore, the scope can be widened by the use of variable nodes. For example, the symbol X means any halogen, the symbol M any metal, and the symbol G allows the user to specify his or her own variable at that point (e.g., G =C1 or NO_2 or Ph). As with an exact search, each answer can be displayed as described above.

As mentioned above, building structures can be very complicated, and, because there is great flexibility in the system, there are a great many ways to use the commands, but the rewards are the retrieval of information that cannot be obtained in any other way. We have given here only a hint of the possibilities in using this system.

It is not necessary to build structures to use the Registry File. Compounds can also be searched for by using names, combinations of name fragments, Registry Numbers, molecular formulas, and in other ways. The display methods are the same.

OTHER DATABASES

Several of the other databases carried by STN are of interest to organic chemists. Among these are BEILSTEIN, which allows Beilstein to be searched online (SSS and EXACT searches can also be done in this database); CASREACTS, in which the user can specify a starting compound and a product, usually by giving Registry Numbers, and the system tells whether that transformation has been reported in the literature (beginning in 1985), and if so gives reagents and references; and CJACS, which gives the complete texts (but not the display material, such as tables and displayed equations) of all papers published in about 20 journals published by the American chemical Society (including *J. Am. Chem. Soc, J. Org. Chem.*, and *Chem. Rev.)* since 1982. chemical journals of several other publishers, including Elsevier *(J. Organomet. Chem.* etc.), VCH (*Angew. Chem. Int. Ed. Engl.*),and the Royal Society of Chemistry *(J. Chem. Soc, Perkin Trans. 1* etc.), are also available online in a similar manner. Having these journals online is particularly useful because their texts can be searched for keywords, author's names, Registry Numbers, and other types of information.

Science Citation Index

A publication that can greatly facilitate literature searching is *Science Citation Index* (*SCI*), begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year that have cited a given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by Jencks and Gilchrist *(J. Am. Chem. Soc,* **1968**, *90,* 2622) entitled "Nonlinear Structure-Reactivity Correlations. The Reactivity of Nucleophilic Reagents toward Esters". The chemist is easily able to begin a search for earlier papers by using references supplied in this paper and can then go further backward with the aid of references in those papers, and so on. But for obvious reasons the paper itself supplies no way to locate *later* papers. The *SCI* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or 2-month period (by first author only), and then gives a list of papers that have done the citing. The index is published bimonthly and cumulated annually. For example, column 43901 of the 1989 citation index shows that the Jencks paper mentioned above was cited as a footnote in 16 papers published in 1989. It is reasonable to assume that most of the papers that cited the Jencks paper were on closely related subjects. For each of the 16 papers are listed the first author, journal abbreviation, volume and page numbers, and year. In a similar manner, if one consulted *SCI* for all the years from 1968 on, one would have a complete list of papers that cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1989 on) for papers that cited these 16 papers, and so on. Papers, patents, or books listed, for example, in the 1989 *SCI* may go back many years (e.g., papers published by Einstein in 1905 and 1906 are included). The only requirement is that a paper published in 1989 (or late 1988) has mentioned the

earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. Cited patents are listed in a separate table, in order of patent number, though the inventor and country are also given.

SCI covers ~ 3200 journals in the physical and biological sciences, as well as in medicine, agriculture, and technology. In addition to the citation index, each bimonthly and annual *SCI* also includes three other indexes. One of these, called *Source Index,* is similar to the *CA* author index. It lists the titles, journal abbreviations, volume, issue, page numbers, and year of all papers published by a given author during that 2-month period or year. All authors are listed; not just first authors. The second, called the *Corporate Index,* lists all publications that have been published from a given institution during that period, by first author. Thus, the corporate index for 1989 lists 63 papers by 45 different first authors emanating from the Department of Chemistry of Rutgers University, New Brunswick, NJ. The main section of the corporate index (the Geographic Section) lists institutions by country or (for the U.S.) by state. There is also an Organization Section, which lists the names of institutions alphabetically, and for each gives the location, so it can be found in the geographic section. The third index included in *SCI* is the *Permuterm*[41] *Subject Index.* This index alphabetically lists every significant word in the titles of all papers published in that year or bimonthly period, paired with all other significant words in the same title. Thus, for example, a title with seven significant words appears at 42 separate places in the index. Each of the seven words appears six times as the main word, each time paired with a different word as the co-word. The user is then led to the *Source Index,* where the full reference is given. The *SCI* is also available online (though not through STN) and on CD-ROM discs. A version of *SCI* that is restricted to chemistry but also includes searchable abstracts, is available only in the CD-ROM format.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews,* that appears semiannually. This publication, which began in 1974, is very similar to *SCI,* but confines itself to listing citations to review articles. The citations come from ~ 2500 journals in the same general areas as are covered by *SCI.* The review articles cited appeared in about 215 review journals and books, as well as in those journals that publish occasional review articles. Like *SCI,* the *Index to Scientific Reviews* contains citation, source, corporate, and Permuterm indexes. It also contains a "Research Front Specialty Index", which classifies reviews by subject.

How to Locate Journal Articles

Having obtained a reference from Beilstein, *SCI, CA,* a treatise, or some other source, one often needs to consult the original journal (the location of patents is discussed on p. 1607). The first step is to ascertain the full name of the journal, since it is the abbreviation that is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals, such as *J. Org. Chem., Chem. Ber.,* but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr. or Nauchn. Tr. Mask. Lesotekh. Inst.*).In such

cases, one consults the *Chemical Abstracts Service Source Index (CASSI)*, 1989 edition, which contains the names of all the journals covered by *CA* from 1907 to 1989 (even those no longer published), with the most recent abbreviations in bold print. The *CASSI* also lists journals covered by *Chemisches Zentralblatt* and its predecessors from 1830 to 1969, and journals cited in Beilstein before 1907. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross-references to the current names. Quarterly supplements, cumulated annually, to *CASSI* have appeared since 1990 listing new journals and recent changes in journal titles. It should be pointed out that, while many publications use the *CA* abbreviations, not all do. The student will find that usages vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations have changed from time to time.

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist. If not, one must use another library, and the next step is to find out which libraries carry the journal. *CASSI* answers this question too, since it carries a list of some 360 libraries in the United States and other countries, and *for each journal it tells which of these libraries carries it*, and furthermore, if the holdings are incomplete, which volumes of that journal are carried by each library. It may be possible to visit the closest library personally. If not, a copy of the article can usually be obtained through interlibrary loan. The *CASSI* also includes lists of journal publishers, sales agents, and document depositories. Photocopies of most documents cited in *CA* can be obtained from chemical Abstracts Document Delivery Service, Customer Services, 2540 Olentangy River Road, Columbus OH, 43210, USA. Orders for documents can be placed by mail, telephone, Telex, fax, or online through STN or other services.

[2] In some journals, notes are called "short communications", an unfortunate practice, because they are not communications as that term is defined in the text.

[3] In Table A.1 notes are counted as papers.

[4] These journals are available in English translation.

[5] These journals also publish review articles regularly.

[6] Each issue of this journal is devoted to a specific topic.

[7] Beginning with 1966 and until 1971, *J. Chem. Soc.* was divided into three sections: *A, B,* and *C.* Starting with 1972, Section *B* became *Perkin Trans. 2* and Section *C became Perkin*

Trans. 1. Section *A* (Physical and Inorganic Chemistry) was further divided into *Faraday* and *Dalton Transactions.*

[8] Before 1987 this journal was called *Nouveau Journal de Chimie.*

[9] Before 1978 this journal was called *Roczniki Chemii.*

[10] *Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.

[11] Before 1989 this journal was called *Reviews of Chemical Intermediates.*

[12] Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences,* which is a similar publication covering biochemistry and medicine.

[13] For example, *Chem. Ind. (London)* publishes abstracts of papers that appear in other journals. In the past, journals such as *J. Am. Chem. Soc, J. Chem Soc,* and *Ber.* also did so.

[14] For a guide to the use of *CA,* see Schulz *From CA to CAS ONLINE;* VCH: NY, 1988.

[15] Beginning in 1967. See p. 1612.

[16] These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

[17] It is possible to subscribe to *CA Selects,* which provides copies of all abstracts within various narrow fields, such as organofluorine chemistry, organic reaction mechanisms, organic stereochemistry, and so on.

[18] An "obituary" of *Zentralblatt* by Weiske, which gives its history and statistical data about its abstracts and indexes, was published in the April 1973 issue of *Chem. Ber.* (pp. I–XVI).

[19] For a discussion of how data are processed for inclusion in Beilstein, see Luckenbach, R.; Ecker, R.; Sunkel, J. *Angew. Chem. Int. Ed. Engl.* **1981,** *20,* 841.

[20] For descriptions of the Beilstein system and directions for using it, see Sunkel, J; Hoffmann, E; Luckenbach, R. *J. Chem. Educ.* **1981,***58,* 982; Luckenbach, R. *CHEMTECH* **1979,** 612. The Beilstein Institute has also published two English-language guides to the system. One, available free, is *How to Use Beilstein;* Beilstein Institute: Frankfurt/Main, **1979.** The other is by Weissbach *A Manual for the Use of Beilstein's Handbuch der Organischen Chemie;* Springer: NY, **1976.** An older work, which many students will find easier to follow, is by Huntress *A Brief Introduction to the Use of Beilstein's Handbuch der Organischen Chemie,* 2nd ed.; Wiley: NY, **1938.**

[21] In some cases, to keep the system parallel and to avoid books that are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

[22] Most page number entries in the combined indexes contain a letter, for example, $CHBr_2Cl$ 67f, II 33a, III 87d, IV, 81. These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter "a" means the compound is the first on its page, "b" is the second, and so on. No letters are given for the fourth supplement.

[25] Pfaltz, A. *Synlett,* **1999,** 835.

[26] Successor to *Quarterly Reviews* (abbreviated as *Q. Rev., Chem. Soc).*

[27] Formerly called *Fortschritte der Chemischen Forschung.*

[28] Smith J. D; Walton D. R. M. *Adv. Organomet. Chem.,* **1975,** *13,* 453.

[29] Bruce M. I. *Adv. Organomet. Chem.,* **1972, 10,** 273, **1973,** *11,* 447, **1974,** *12,* 380.

[30] Belen'kii L. I. *Adv. Hetemcycl. Chem., 1988, 44,* 269; Katritzky A. R.; Jones P. M. *Adv. Heterocycl.Chem.,1979, 25,* 303; Katritzky A. R.; Weeds S. M. *Adv. Hetemcycl. Chem., 1966, 7,* 225.

[31] Compounds newly reported in the fifth supplement that are in a volume whose index has not yet been published will not be found by this procedure. To find them in Beilstein it is necessary to know something about the system (see Ref. 21), but they may also be found by consulting *CA* indexes beginning with the sixth collective index, or by using Beilstein online.

[32] For those heterocyclic compounds that would naturally belong to a volume for which the fifth supplement has been published.

[32a] For a monograph that covers both online searching and searching using printed materials, see Wiggins, G. *Chemical Information Sources;* McGraw-Hill: NY, *1991.*

[33] This discussion is necessarily short. For much more extensive discussions, consult the books in Refs. 1 and 15.

[34] There is also a file called CAOLD that has some papers earlier than 1967.

[35] For a discussion of *CA* online, see Ref. 15.

[36] There is also a file, LCA, which is used for learning the system. It includes only a small fraction of the papers in the CA File, and is not updated. There is no charge for using the LCA File, except for a small hourly fee.

[37] Most commands can be used in three ways, as shown here. When the full term is spelled out (SEARCH), the system assumes an unsophisticated user, and gives more help. If the command is S, the system assumes the user is knowledegable about the system.

[38] For some papers in the late 1960s only the bibliographic data, and not the abstracts, are available online.

[39] If we ask for AMBIDENT NUCLEOPHILE without the (W), the system treats it as if we asked for AMBIDENT(W)NUCLEOPHILE, and gives the same answers.

[40] The structures shown in Figure A.1 are those received by ordinary computer terminals. Better looking structures, more like those printed in books, are obtained with certain types of terminals. The system always asks the user to specify which type of terminal is being used.

[41] Registered trade name.

APPENDIX B

Classification of Reactions By Type of Compound Synthesized

Acetals and Ketals

10-12	Reaction between alkoxides and *gem*-dihalides (Williamson) or α-halo ethers
10-15	Reaction between diazoalkanes and alcohols
10-17	Transetherification
10-84	Reduction of ortho esters
10-101	Reaction between Grignard reagents and ortho esters
14-7	Cyclization of (3-hydroxy ethers
15-5	Addition of alcohols or phenols to triple bonds
16-5	Addition of alcohols to aldehydes or ketones
16-53	Addition of aldehydes to alkenes (Prins)
16-58	Trimerization and polymerization of aldehydes

Acetoxy Sulfides

19-62	Pummerer rearrangement

Acetylenes *{see* Alkynes)

Acids *(see* Carboxylic Acids, Sulfonic Acids)

Acylals

15-6	Addition of carboxylic acids to alkynes
16-57	Acylation of aldehydes or ketones
19-13	Bisdecarboxylation of malonic acids
19-16	Oxidation of arylmethanes with CrO_3 and Ac_2O

Acyl Halides

10-3	Reaction between 1,1,1 -trihalides and SO3
10-77	From carboxylic acids
10-78	Conversion of acid derivatives to acyl halides

14-3 Halogenation of aldehydes
15-2 Addition of hydrogen halides to ketenes
15-28 Free-radical addition of acyl halides to alkenes
19-22 Oxidation of alcohols

Acyloxy Ketones

15-55 Addition of an acyl and an acyloxy group to a double bond

Acyloins *(see* Hydroxy Aldehydes and Ketones)

Alcohols *(see also* Diols, Hydroxy Esters, etc.)

10-1 Hydrolysis of alkyl halides
10-4 Hydrolysis of inorganic esters
10-6 Hydrolysis of enol ethers, acetals, or ortho esters
10-10 Hydrolysis of carboxylic esters
10-17 Transetherification
10-18 Payne rearrangement
10-20 Oxidation of silanes
10-24 Transesterification
10-34 From amines by reaction of KNO_2 and sulfonamides
10-58 Ammonolysis of carboxylic esters
10-71 Cleavage of ethers with concentrated acids
10-84 Reduction of acetals or ortho esters
10-85 Reduction of epoxides
10-92 Coupling of allylic silanes and epoxides
10-101 Cleavage of acetals or ortho esters with Grignard reagents
10-102 Reaction between organometallic compounds and epoxides
10-107 Alkylation of alcohols
10-124 Hydrolysis of sulfonic esters
11-12 Alkylation of aromatic rings with ethylene oxide
11-22 Hydroxyalkylation of aromatic rings
12-25 Reaction between organometallic reagents and oxygen
14-4 Hydroxylation at an aliphatic carbon
14-23 Free-radical hydroxymethylation of aromatic rings
15-3 Hydration of alkenes and of cyclopropanes
15-16 Hydroboration–oxidation of alkenes
15-24 Addition of organometallic compounds to unsaturated alcohols
15-26 Addition of CH_3 and H to allylic alcohols
15-28 Free-radical addition of alcohols to alkenes
15-54 Addition of OH and SR to double bonds
16-23 Reduction of aldehydes or ketones
16-27 Addition of Grignard reagents and organolithium reagents to aldehydes or ketones

16-28	Addition of organometallic compounds to aldehydes or ketones
16-33	Addition of Grignard reagents to carboxylic esters or acyl halides
16-50	Addition of allylic silanes to aldehydes
16-53	Reductive addition of alkenes to aldehydes
16-55	Addition of radicals to ketones and aldhydes
17-2	Alkaline cleavage of ethers
17-32	Reaction of N-substituted amides with certain catalysts
18-1	Rearrangement of alcohols or alkenes (Wagner-Meerwein)
18-3	Expansion and contraction of rings (Demyanov)
18-19	Cleavage of methyl ketones with peracids (Baeyer–Villiger)
18-20	Cleavage of hydroperoxides
18-22	Rearrangement of ethers upon treatment with alkyllithiums (Wittig)
18-23	From boranes and CO, or CN^-, or $CHCl_2OMe$
18-23	From boranes, CO, water, and NaOH
18-24	From boranes, CO, and $LiAlH_4$
18-35	[2,3] Sigmatropic rearrangements of allylic ethers or allylic sulfoxides
19-9	Reduction of ozonides
19-34	Reduction of carboxylic acids
19-38	Reduction of carboxylic esters
19-39	Reduction of carboxylic esters with titanocene dichloride
19-37	Reduction of anhydrides
19-37	Reduction of acyl halides
19-46	Reduction of nitriles
19-60	Reaction between aldehydes and base (Cannizzaro)

Aldehydes *(see also* Dicarbonyl Compounds, Unsaturated Carbonyl Compounds, etc.)

10-2	Hydrolysis of *gem*-dihalides
10-4	Hydrolysis of enol esters of inorganic acids
10-6	Hydrolysis of enol ethers, acetals, thioacetals, and so on
10-10	Hydrolysis of enol esters
10-89	Reduction of acyl halides
10-90	Reduction of carboxylic acids, esters, or anhydrides
10-91	Reduction of amides
10-105	Alkylation and hydrolysis of imines; alkylation of aldehydes
10-107	Alkylation and hydrolysis of dithianes
10-108	Alkylation and hydrolysis of oxazines and similar compounds
10-109	Reaction of diazo aldehydes with boranes
10-112	Carbonylation of alkyl halides
10-115	Reaction between formates or formamides and organometallic compounds
10-120	Formylation of carboxylic acid salts
10-123	Reaction between formic acid, another acid, and thorium oxide

11-15	Formylation of aromatic rings with formamides and $POCl_3$ (Vilsmeier)
11-16	Formylation of aromatic rings with Zn(CN)2 and HCl (Gatterman)
11-17	Formylation of aromatic rings with chloroform (Reimer–Tiemann)
11-18	Other formylations of aromatic rings
12-25	Oxidation of 1,1-dimetallic compounds
12-31	Carbonylation of organometallic compounds
12-39	Decarboxylation of glycidic acids
13-13	Carbonylation of aryl iodides
13-15	Vicarious substitution of aryl nitro compounds
14-15	Cross-coupling of alkanes with trioxane
14-19	Arylation of allylic alcohols
14-30	Reaction of diazonium salts with oximes, followed by hydrolysis
15-3	Cleavage of activated alkenes with water
15-4	Hydration of acetylene
15-13	Selective reduction of unsaturated aldehydes
15-16	Oxidation of boranes; hydrolysis of unsaturated boranes
15-24	Addition of organometallic compounds to unsaturated aldehydes
15-25	Addition of boranes to unsaturated aldehydes
15-31	Hydroformylation of alkenes (oxo process)
16-2	Hydrolysis of imines, oximes, hydrazones, or other C=N compounds
16-3	Hydrolysis of primary nitro compounds (Nef)
16-26	Reduction of nitriles
16-33	Addition of Grignard reagents to formamides
16-41	Reaction of aldehydes or ketones with boron methides
16-67	Hydrolysis of metalated aldimines
17-1	Dehydration of 1,2-diols
17-2	Pyrolysis of vinylic ethers
17-25	Fragmentation of y-amino or y-hydroxy halides
17-26	Fragmentation of 1,3-diols
17-31	Fragmentation of certain ketoximes
17-34	Pyrolysis of (3-hydroxy alkenes
18-2	Rearrangements of diols (pinacol)
18-9	Homologation of aldehydes
18-13	Reaction between α-hydroxy or α-halo amides and NaOBr (Hofmann)
18-20	Cleavage of hydroperoxides
18-22	Rearrangement of allylic ethers
18-24	Treatment of boranes with CO and $LiAl(OMe)_3$
18-30	[1,3] Sigmatropic rearrangements of allylic vinylic ethers
18-40	Photolysis of nitrites, followed by hydrolysis (Barton)
19-5	Oxidation of primary alcohols
19-7	Oxidative cleavage of glycols or related compounds
19-9	Ozonolysis of alkenes
19-12	Oxidation of arylacetic acids

19-14 Oxidation of activated methyl groups
19-16 Oxidation of arylmethanes (Étard)
19-19 Oxidation of primary halides or esters of primary alcohols
19-20 Oxidation of amines or nitro compounds
19-22 Oxidation of alkenes with noble metal salts
19-62 Hydrolysis of α-acetoxy sulfides

Alicyclic Compounds

10-93 Internal coupling (Wurtz)
10-97 Cyclization of diallylic halides
10-99 Cyclization of 1,3-diols
10-104 Internal malonic ester synthesis
10-112 Carbonylation of 1,4-dihalides
10-118 Internal condensation of diesters (Dieckmann)
10-123 Ketonic decarboxylation of dicarboxylic acids
11-12 Intramolecular Friedel-Crafts alkylation
11-13 Scholl ring closure
11-14 Intramolecular Friedel-Crafts acylation
11-23 Cyclodehydration of aldehydes and ketones
12-15 Intramolecular insertion of carbocations
12-19 Intramolecular insertion of carbenes
13-14 Cyclization of dihalobiphenyls
14-16 Coupling of terminal diynes (cycloalkynes)
14-17 Intramolecular arylation (Pschorr)
14-31 Cyclization of dimagnesio compounds
15-14 Reduction of aromatic rings
15-19 Cyclization of dienes or diynes
15-24 Cyclization of unsaturated Grignard reagents
15-26 Free radical cyclization of alkenes with tin or mercury halides
15-28 Cyclization of unsaturated aldehydes
15-31 Carbonylation of dienes
15-35 Radical cyclization
15-44 Cyclization of halo alkenes
15-58 Addition of alkenes to dienes (Diels–Alder)
15-60 All-carbon 2 + 3 cycloadditions
15-61 Dimerization of alkenes
15-62 Addition of carbenes or carbenoids to alkenes or alkynes
15-63 Tetramerization of alkynes
15-64 Other cycloaddition reactions
16-27 Ring closure of halo carbonyl compounds
16-33 Reaction between carboxylic esters and dimagnesium compounds
16-38 Internal aldol reactions
16-39 Internal Mukaiyama aldol reactions
16-47 Internal Wittig reactions

16-49	Cyclization of dinitriles (Thorpe–Ziegler)
17-36	Extrusion of N_2 from pyrazolines or pyrazoles
17-37	Extrusion of CO from cyclic ketones
17-38	Extrusion of SO_2 from cyclic sulfones
17-39	Decarboxylation of cyclic peroxides (Story)
18-1	Wagner-Meerwein rearrangements to give cyclic products
18-3	Expansion and contraction of rings
18-7	Ring contraction of halo ketones (Favorskii)
18-8	Ring contraction of cyclic diazo ketones (Wolff)
18-9	Ring expansion of cyclic ketones
18-23	Treatment of cyclic boranes with CO
18-27	Cyclization of conjugated dienes and trienes
18-30	[1,7] Sigmatropic migrations of carbon
18-31	Ring expansion of vinylcyclopropenes and cyclobutenes
18-32	Ring expansion of vinylcycloalkanes; cyclization of diynes
18-37	Metathesis of dienes
18-38	Metal-ion-catalyzed σ-bond rearrangements
18-39	The di-π-methane rearrangement
19-2	Dehydrogenative ring closing
19-30	Oxidative cyclization
19-55	Reductive cyclization of dialdehydes
19-56	Cyclization of diketones or keto esters
19-57	Condensation of diesters (acyloin)

Alkanes *(see also* Alicyclic Compounds)

10-79	Reduction of alkyl halides
10-80	Reduction of tosylates and similar compounds
10-81	Hydrogenolysis of alcohols
10-82	Hydrogenolysis of esters (Barton–McCombie Reaction)
10-83	Hydrogenolysis of nitriles
10-86	Reductive cleavage of carboxylic esters
10-87	Reduction of the C—N bond
10-88	Reductive cleavage of thiols, sulfides, and sulfoxides
10-93	Coupling of alkyl halides (Wurtz)
10-94	Coupling of alkyl halides with groups I and II organometallic reagents
10-95	Coupling of alkyl halides with organocuprates
10-96	Coupling of alkyl halides with organometallic reagents other than Cu and groups I or II
10-98	Reaction between organometallic reagents and alkyl sulfates or sulfonates
10-99	Coupling of alcohols
10-101	Reaction between Grignard reagents and ethers
10-107	Reduction of dithianes

11-40 Deoxygenation of aryl ethers
12-17 Alkylation of alkanes
12-19 Insertion of carbenes
12-23 Reaction between organometallic compounds and acids
12-38 Decarboxylation of carboxylic acids
12-39 Cleavage of tertiary alkoxides
12-43 Cleavage of nonenolizable ketones
12-44 Cleavage of ketones with amide ion (Haller–Bauer)
12-45 Cleavage of alkanes
12-46 Decyanation of nitriles
14-15 Coupling of alkanes
14-31 Coupling of Grignard reagents
14-32 Coupling of boranes
14-33 Coupling of other organometallic compounds
14-34 Desulfurization of sulfur compounds
14-36 Decarboxylative dimerization (Kolbe)
14-39 Decarbonylation of aldehydes or acyl halides
15-11 Hydrogenation of alkenes and alkynes
15-12 Reduction of alkenes and alkynes
15-14 Reduction of aromatic rings
15-15 Reductive cleavage of cyclopropanes
15-18 Addition of alkanes to alkenes
15-19 Dimerization of alkenes
15-22 Addition of organometallics to alkenes and alkynes
15-35 Radical addition to alkenes
16-28 Reaction of ketones with trimethylaluminum
16-33 Reaction of carboxylic acids with trimethylaluminum
17-37 Extrusion of CO_2 from diacyl peroxides
19-6 Oxidation of hydrazines
19-12 Oxidative decarboxylation of carboxylic acids
19-33 Reduction of aldehydes or ketones (Wolff–Kishner; Clemmensen)
19-39 Reduction of carboxylic acids or esters
19-40 Reduction of epoxides
19-46 Reduction of cyano to methyl groups

Alkenes *{see also* Alicyclic Compounds, Unsaturated Acids, Unsaturated Alcohols, etc.)

10-79 Reduction of unsaturated halides
10-81 Reduction of allylic alcohols
10-87 Reductive cleavage of enamines
10-92 Coupling of allylic silanes and alkyl halides
10-93 Coupling of vinylic halides
10-94 Coupling of unsaturated halides with organometallic reagents
10-97 Coupling of allylic halides, tosylates, or acetates

10-98	Coupling of vinylic triflates with organometallic reagents
10-99	Coupling of allylic alcohols with organometallic reagents
10-100	Coupling of allylic esters with organometallic reagents
10-101	Cleavage of allylic, vinylic, or silyl ethers
12-2	Migration of double and triple bonds
12-38	Decarboxylation of unsaturated acids
14-18	Arylation of alkenes (Meerwein)
14-19	Arylation of alkenes by organopalladium compounds
14-29	Vinylation of diazonium salts
14-31	Dimerization of allylic Grignard reagents
14-32	Dimerization of vinylic chloroboranes
14-33	Dimerization of vinylic organometallic reagents
14-34	Desulfurization of thiophenes
14-36	Additive dimerization of alkenes and carboxylic acids
15-1	Isomerization of double bonds
15-11	Hydrogenationm of alkynes or allenes
15-14	Reduction of aromatic rings
15-16	Reduction of vinylic boranes; hydroboration of enamines
15-19	Dimerization of alkenes; dimerization of alkynes
15-20	The ene synthesis
15-24	Reaction of allylic halides, alkynes, and zinc
15-58	Addition of alkenes to dienes (Diels–Alder)
15-62	Addition of carbenes to aromatic rings
15-63	Tetramerization of alkynes
15-64	Dimerization of dienes
15-23	Addition of two alkyl groups to an alkyne
16-27	Reaction of *gem*-dimetallic compounds or organolithium compounds with aldehydes or ketones
16-31	Reformatsky reaction with Bu_3P
16-48	Reaction of ketones with Tebbe's reagent
16-41	From tosylhydrazone salts
16-42	Addition to aldehydes or ketones of α-sulfinyl carbanions or of α-lithiosilanes (Peterson)
16-47	Reaction between phosphorus ylids and aldehydes or ketones (Wittig)
16-48	Tebbe, Petasis and alternative alkenylations
16-62	Reaction of sulfonyl halides with tertiary amines and diazoalkanes
17-1	Dehydration of alcohols
17-2	Alkaline cleavage of ethers
17-3	Pyrolysis of carboxylic esters
17-4	Pyrolysis of xanthates (Chugaev)
17-5	Cleavage of inorganic esters and sulfonates
17-6	Cleavage of quaternary ammonium hydroxides (Hofmann)
17-7	Cleavage of quaternary ammonium salts
17-8	Cleavage of amine oxides (Cope)

17-10 Decomposition of tosylhydrazones
17-11 Cleavage of sulfoxides, selenoxides, and sulfones
17-12 Dehydrohalogenation of alkyl halides
17-13 Reaction of sulfonyl halides with tertiary amines
17-14 Elimination of boranes
17-16 Decarbonylation of acyl halides
17-17 Deoxygenation of *vic*-diols
17-18 Cleavage of cyclic thionocarbonates
17-19 Deoxidation of epoxides
17-20 Reaction of α-halo sulfones with bases (Ramberg–Bäcklund)
17-21 Reaction of aziridines with nitrous acid
17-22 Dehalogenation of *vic*-dihalides
17-24 Elimination of a halo and a hetero group (Boord)
17-25 Fragmentation of y-amino or y-hydroxy halides
17-26 Fragmentation of 1,3-diols
17-27 Decarbonylation of P-hydroxy carboxylic acids and of β-lactones
17-29 Elimination of CO and CO_2 from bridged bicyclic compounds
17-34 Pyrolysis of P-hydroxy alkenes
17-40 Twofold extrusion from certain cyclic molecules
18-1 Rearrangement of alcohols and alkenes (Wagner-Meerwein)
18-7 Expansion and contraction of rings (Demyanov)
18-8 Rearrangement of carbenes or carbenoids
18-25 Reaction between vinylic boranes and iodine or NaOMe
18-26 Reaction of lithium alkynyltrialkylborates with electrophiles
18-27 Electrocyclic rearrangements of cyclobutenes and cyclohexadienes
18-29 [1, *j*] Sigmatropic migrations of hydrogen
18-30 [1, *j*] Sigmatropic migrations of carbon
18-31 Rearrangement of vinylcyclopropanes
18-32 Rearrangement of 1,5-dienes (Cope)
18-37 Metathesis of alkenes
18-38 Cyclobutane reversions
18-39 The di-π-methane rearrangement
19-2 Dehydrogenation of diarylalkanes; remote dehydrogenation
19-12 Oxidative decarboxylation of carboxylic acids
19-13 Bisdecarboxylation of succinic acids
19-30 Oxidative coupling of halides
19-33 Reduction of α-hydroxy ketones; of unsaturated tosylhydrazones
19-56 Bimolecular reduction of aldehydes or ketones

Alkyl Halides *(see also* Dihalides, Halohydrins, etc.)

10-20 Fluoride displacement of arylsilanes
10-68 Halide exchange (Finkelstein)
10-69 Reaction between inorganic esters and halide ions
10-70 Reaction between alcohols and hydrogen halides or inorganic acid halides

10-71 Cleavage of ethers with HI or HBr
10-73 Cleavage of carboxylic esters with LiI
10-75 Conversion of amines to halides
10-76 Cleavage of tertiary amines (von Braun)
10-79 Reduction of dihalides
10-85 Reductive halogenation of epoxides
10-101 Homologation of alkyl halides
10-107 Homologation of alkyl halides
11-12 Reaction between aromatic rings and carbon tetrachloride
11-24 Haloalkylation of aromatic rings
12-30 Halogenation of organometallic compounds
12-38 Exchange between halides and organometallic compounds
14-1 Free-radical halogenation
14-2 Allylic halogenation
14-37 Decarboxylative halogenation (Hunsdiecker)
15-2 Addition of hydrogen halides to alkenes or alkynes
15-28 Free-radical addition of alkyl halides to alkenes
15-37 Addition of halogens to alkenes or alkynes
15-44 Addition of alkyl or aryl halides to alkenes
16-22 Reductive halogenation of aldehydes
16-28 Addition of methylniobium reagents to ketones
17-32 Reaction of N-substituted amides with PCl_5 (von Braun)

Alkynes *(see also* Alkynyl Halides, Alkynyl Ethers)

10-81 Reduction of acetylenic alcohols
10-94 From allenic substrates, with organocopper reagents
10-97 Propargylation of alkyl halides
10-110 Alkylation at an alkynyl carbon
12-2 Triple-bond migration
12-38 Decarboxylation of acetylenic acids
13-11 Reaction between aryl iodides and copper acetylids
14-16 Coupling of alkynes (Eglinton)
14-19 Arylation of alkynes
14-31 Dimerization of alkynyl organometallic compounds
14-32 Coupling of alkynyl borates
17-6 Pyrolysis of bisquaternary ammonium hydroxides
17-11 Cleavage of selenoxides
17-12 Dehydrohalogenation of dihalides or vinylic halides
17-15 Elimination of the elements of CH4 from certain alkenes
17-20 Decomposition of thiiren-1,1 -dioxides
17-22 Dehalogenation of tetrahalides
18-26 From boranes and lithium acetylids
18-37 Metathesis of alkynes
19-2 Dehydrogenation of certain diaryl alkenes

19-30 Oxidation of dihalotoluenes

Alkynyl Ethers

17-12 Reaction between vinylidine dihalides and amide ion

Alkynyl Halides

12-28 Reaction of acetylide ions with halogens

Allenes

10-79 Reduction of propargyl halides
10-86 Reduction of propargyl acetates
10-97 Alkylation of propargyl halides
10-98 Alkylation of propargyl tosylates
10-100 Reaction between propargyl esters and organometallic reagents
10-101 Cleavage of propargyl ethers by Grignard reagents
12-2 Rearrangement of alkynes
16-47 Reaction of phosphoranes with ketenes or CO_2
16-48 Tebbe, Petasis and alternative alkenylations
17-12 Dehydrohalogenation of dihalides
17-22 Dehalogenation of tetrahalides or dihaloalkenes
17-34 Pyrolysis of P-hydroxy alkynes
18-3 Contraction of three-membered rings
18-33 Rearrangement of propargylic vinyl compounds

Amidals *(see* Bisamides)

Amides *(see also* Bisamides)

10-11 Cleavage of an alkyl group from N-*tert*-butyl amides
10-48 Transamidation
10-54 Reaction between secondary amines and chloroform
10-55 Amination of acyl halides
10-56 Amination of anhydrides
10-57 Amination of carboxylic acids
10-58 Amination of carboxylic esters
10-59 Amination of amides
10-60 Amination of other acid derivatives
10-61 N-Alkylation of amides
10-113 Carbonylation of alkyl halides
11-6 Amidation of aromatic rings with hydroxamic acids
11-19 Carbamoylation of aromatic rings (Gatterman)
11-21 Amidation of aromatic rings with isocyanates
11-25 Amidoalkylation of aromatic rings

11-34	Rearrangement of N-halo-N-acyl aromatic amines (Orton)
12-12	Insertion by nitrenes
12-29	Indirectly from aldehydes
12-30	From imines, CO, and a borane
12-40	Reaction between amino acids and anhydrides (Dakin-West)
12-44	Cleavage of ketones with amide ion (Haller–Bauer)
12-46	Decyanation of cyano amides
12-53	Carbonylation of amines
13-5	N-Arylation of amides
13-13	Carboamidation of aryl halides
14-13	Reaction of aldehydes with ammonia
14-14	Amidation at an alkyl carbon
14-23	Carboamidation of nitrogen heterocycles
15-4	Hydration of ynamines
15-8	Addition of amides to alkenes; addition of amines to ketenes
15-9	Addition of amides to alkenes
15-28	Free-radical addition of amides to alkenes
15-29	Carbonylation of Double and Triple Bonds in the presence of amines
15-30	Hydrocarboxylation of alkenes in the presence of amines
16-4	Partial hydrolysis of nitriles
16-14	Reductive alkylation of amines (Leuckart)
16-17	Addition of amines and water to nitriles
16-24	Reduction of isocyanates
16-56	Addition of alcohols or other carbocation sources to nitriles (Ritter)
16-65	Addition of water to isocyanides
18-7	Rearrangement of α-halo ketones in the presence of amines (Favorskii)
18-8	Rearrangement of diazo ketones in the presence of amines (Arndt-Eistert)
18-13	Reaction between amides, lead tetraacetate, and acetic acid
18-16	Reaction between ketones and hydrazoic acid (Schmidt)
18-17	Rearrangement of oximes (Beckmann)
18-42	Rearrangement of aryl imidates (Chapman)
19-17	Oxidation of tertiary amines
19-52	de-Alkylation of amides
19-63	Oxidation of aryl ketones with ammonium polysulfide (Willgerodt)

Amidines

10-58	Amination of imidates
15-8	Addition of amines to ketenimines
16-17	Addition of ammonia or amines to nitriles

Amido Ketones

15-55	Addition of an acyl group and an acylamino group to a double bond

Aminals

16-12 Addition of amines to aldehydes or ketones

Amine Oxides

19-27 Oxidation of tertiary amines

Amines *(see also* Cyanoamines, Amino Acids, etc.)

10-11 Hydrolysis of amides
10-38 Cleavage of amines or quaternary ammonium salts
10-44 Alkylation of ammonia or amines
10-45 Coupling of amines and aryl halides
10-46 From alcohols or ethers
10-47 Transamination
10-49 Alkylation of amines with diazo compounds
10-52 Reaction of amines with aziridines
10-53 Amination of alkanes
10-61 Hydrolysis of phthalimides (Gabriel); and so on
10-75 Cleavage of aromatic amines or quaternary ammonium salts
10-87 Reduction of quaternary ammonium salts or aziridines
10-101 Cleavage of amine ethers with organometallic compounds
10-102 Reaction of organometallic compounds with aziridines
10-103 Reaction of organometallics with aziridines
10-107 Alkylation of amines
10-124 Hydrolysis of sulfonamides
11-6 Direct amination of aromatic rings
11-25 Aminoalkylation of aromatic rings
11-31 Rearrangement of N-nitroamines
11-32 Rearrangement of N-nitrosoamines (Fischer-Hepp)
11-33 Rearrangement of triazenes
11-35 Rearrangement of arylamines or aryl alkyl ammonium salts
12-11 Amination at an activated position
12-29 Conversion of organometallic compounds to amines
12-38 Decarboxylation of amino acids
12-46 Decyanation of cyanoamines
13-5 Arylation of ammonia or amines
13-6 Reaction between naphthols, bisulfite ion, and ammonia or amines (Bucherer)
13-16 Amination of heterocyclic nitrogen compounds (Chichibabin)
13-22 Rearrangement of benzylic quaternary ammonium salts (Sommelet–Hauser)
13-23 Rearrangement of aryl hydroxylamines
14-9 Demethylation of tertiary amines
14-34 Desulfurization of thioamides
15-8 Addition of ammonia or amines to alkenes

15-24	Addition of organometallic compounds to allylic amines
15-28	Free-radical addition of amines to alkenes
15-52	Diamination of alkenes
15-54	Addition of R_2N and SR to double bonds
15-59	Heteroatom Diels Alder reaction of imines
16-2	Hydrolysis of imines, enamines, and iminium ions
16-4	Hydrolysis of cyanamides
16-14	Reductive alkylation of ammonia or amines
16-15	Reaction between aldehydes, ammonia or amines, and an active hydrogen compound (Mannich)
16-24	Reduction of imines, hydrazones, or other compounds containing the C=N bond
16-25	Reduction of nitriles or nitrilium ions
16-27	Addition of Grignard reagents and organolithium reagents to amides
16-28	Addition of organometallic compounds to amides
16-33	Addition of Grignard reagents to formamides
16-35	Addition of Grignard reagents to imines
16-55	Addition of radicals to imines
17-6	Cleavage of quaternary ammonium hydroxides (Hofmann)
17-7	Cleavage of quaternary ammonium salts
17-31	Fragmentation of certain ketoximes
18-13	Reaction between amides and NaOBr (Hofmann)
18-14	Rearrangement of acyl azides in the presence of water (Curtius)
18-15	Rearrangement of hydroxamic acids and acyl halides (Lossen)
18-16	Addition of hydrazoic acid to carboxylic acids (Schmidt)
18-18	Rearrangement of N-haloamines
18-21	Rearrangement of quaternary ammonium salts and tertiary benzylic amines (Stevens)
18-35	[2,3] Sigmatropic rearrangements of quaternary ammonium salts
18-36	Rearrangement of benzidines
18-40	Hofmann–Löffler and related reactions
19-5	Conversion of primary to secondary amines by dehydrogenation
19-9	Reaction between ozonides, ammonia, and hydrogen
19-20	Oxidative cleavage of amines
19-35	Reduction of amides
19-41	Reduction of nitro compounds
19-43	Reduction of nitroso compounds or hydroxylamines
19-44	Reduction of oximes
19-45	Reduction of azides
19-46	Reduction of isocyanates, isothiocyanates, or N-nitroso compounds
19-48	Reduction of amine oxides
19-52	de-Alkylation of amines
19-53	Reduction of azo, azoxy, or hydrazo compounds
19-55	Bimolecular reduction of imines (1,2-diamines)

Amino Acids and Esters

10-11	Hydrolysis of lactams
10-44	Amination of halo acids
10-58	Ammonolysis of β-lactones
10-104	Alkylation of N-acetylaminomalonic esters (Sorensen)
12-8	Nitrosation at a carbon bearing an active hydrogen and reduction of the resulting oxime or nitroso compound
12-11	From acyl halides and a dialkyl azodicarboxylate
16-4	Hydrolysis of cyanohydrins
16-15	Reaction between aldehydes, ammonia, and carboxylic acids or esters
16-51	Addition of cyanide and ammonium ions to aldehydes or ketones, followed by hydrolysis (Strecker)
18-13	Reaction between imides and NaOBr (Hofmann)

Amino Carbonyl Compounds

10-46	Amination of α-hydroxy ketones
10-47	Transamination of Mannich bases
11-35	Photolysis of acylated arylamines
16-15	Reaction between aldehydes, ammonia, and aldehydes, ketones, or esters (Mannich)
18-12	Rearrangement of ketoxime tosylates (Neber)
18-21	Rearrangement of quaternary ammonium salts (Stevens)
19-22	Oxidation of certain enamines

Amino Ethers

10-18	Alcoholysis of aziridines
15-51	Aminomercuration of alkenes, followed by alcoholysis
16-15	Reaction between aldehydes, amines, and alcohols or phenols (Mannich)

Amino Thiols

10-50	Amination of episulfides
11-9	Sulfurization of aromatic amines (Herz)
16-15	Reaction between an aldehyde, ammonia, and a thiol (Mannich)

Anhydrides

10-29	Reaction of acyl halides with acid salts
10-30	Dehydration of carboxylic acids
10-35	Reaction of acid derivatives with inorganic acids

13-13	From aryl halides and CO
14-10	Acyloxylation of aldehydes
14-30	Reaction between diazonium fluoroborates, CO, and an acid salt
15-6	Addition of carboxylic acids to ketenes
15-28	Free-radical addition of anhydrides to alkenes
18-19	Reaction between α-diketones and peroxy compounds (Baeyer-Villiger)
19-10	Oxidation of aromatic rings

Arenes

10-79	Reduction of aryl and benzylic halides
10-81	Hydrogenolysis of benzyl alcohols
10-84	Reduction of benzylic ethers
10-93	Coupling of halides containing aryl groups
10-94	Coupling of aryl halides with organometallic reagents
10-99	Coupling of benzylic alcohols
11-12	Alkylation of aromatic rings (Friedel-Crafts)
11-13	Arylation of aromatic rings (Scholl)
11-22	Diarylation of ketones
11-23	Ring closure of aryl-substituted carbonyl compounds
11-36	Cleavage or rearrangement of alkyl arenes
11-37	Decarbonylation of aromatic aldehydes or deacylation of aromatic ketones
11-38	Decarboxylation of aromatic acids
11-41	Desulfonation of aromatic sulfonic acids
11-42	Dehalogenation of aryl halides
11-44	Hydrolysis of organometallic compounds
12-38	Decarboxylation of α-aryl acids
12-39	Cleavage of tertiary alkoxides
12-43	Cleavage of aryl ketones
12-44	Cleavage of aryl ketones with amide ions (Haller–Bauer)
12-46	Decyanation of aryl nitriles
13-8	Reduction of phenols, phenolic ethers, or phenolic esters
13-9	Reduction of aromatic nitro compounds
13-11	Coupling of organometallic compounds with aryl halides, ethers, and esters
13-14	Coupling of aryl iodides (Ullmann)
13-15	Alkylation with organometallic compounds
14-17	Free-radical arylation by diazonium salts (Gomberg–Bachmann, Pschorr)
14-21	Free-radical arylation by peroxides
14-22	Photochemical arylation
14-24	Reduction of diazonium salts
14-28	Dimerization of diazonium salts

14-29 Methylation of diazonium salts
14-31 Coupling of Grignard reagents
14-32 Coupling of arylboranes
14-33 Coupling of other organometallic compounds
14-34 Reduction of sulfur compounds
14-36 Coupling of aromatic acyl halides, with decarbonylation
14-39 Decarbonylation of aromatic aldehydes
15-26 Addition of tin and mercury hydrides to aryl alkenes
15-63 Trimerization of alkynes
16-27 Alkylation-reduction of aromatic aldehydes and ketones
17-29 Diels–Alder reactions of cyclopentadienones with alkynes
18-28 Photoconversion of stilbenes to phenanthrenes
19-1 Aromatization of six-membered rings
19-6 Oxidation of hydrazines
19-30 Dimerization of arenes
19-33 Reduction of aromatic aldehydes
19-39 Reduction of aromatic acids

Aryl Halides

11-11 Halogenation of aromatic compounds
11-34 Rearrangement of N-haloamines (Orton)
11-38 Replacement of aromatic COOH by halogen
11-41 Replacement of aromatic SO_2Br by halogen
11-42 Migration of halogen
12-28 Reaction of aryl organometallic compounds with halogens
13-7 Aryl halide exchange; halo-denitration; halo-dehydroxylation
13-19 Reaction between diazonium salts and iodide ion
13-20 Heating of diazonium fluoroborates (Schiemann)
14-25 Reaction between diazonium salts and CuCl or CuBr (Sandmeyer)
14-37 Decarboxylative halogenation (Hunsdiecker)
14-39 Decarbonylation of acyl halides

Azides

10-65 Alkylation or acylation of azide ion
12-10 Treatment of amides with tosyl azide
12-48 Reaction between hydrazines and nitrous acid
14-37 Reaction of acyl peroxides with copper azide
15-10 Addition of hydrazoic acid to double bonds
15-43 Addition of halogen azides to double bonds
15-52 Treatment of alkenes with sodium azide, ferrous ion, and hydrogen peroxide
15-54 Addition of SR and N_3 to double bonds
18-14 Reaction between hydrazides and nitrous acid
18-16 Reaction between alcohols or alkenes and hydrazoic acid

Azido Amides

12-10 Azidation of amides

Azines

16-19 Addition of hydrazine to aldehydes or ketones

Aziridines

10-44 Cyclization of haloamines
10-46 Cyclization of amino alcohols
10-63 Formation of aziridines from epoxides
10-65 Cyclization of P-azido alcohols
15-43 From P-iodo azides
15-53 Reaction of alkenes with azides
16-36 Addition of carbenes and diazoalkanes to imines
16-45 Reaction of imines with α-halo carbonyl compounds
17-36 Extrusion of N_2 from triazolines
19-44 Reduction of oximes

Azo Compounds

11-4 Coupling of diazonium salts with aromatic rings
11-33 Rearrangement of aryl triazenes
12-7 Aliphatic diazonium coupling
12-50 Reaction of amines with nitroso compounds (Mills)
12-51 From aromatic nitro compounds
14-28 Coupling of aryl diazonium salts
18-43 Rearrangement of azoxy compounds (Wallach)
19-6 Oxidation of hydrazines
19-48 Reduction of azoxy compounds
19-59 Reduction of nitro compounds

Azoxy Compounds

10-67 Reaction between alkyl halides and alkanediazotates
12-51 Reaction of nitroso compounds with hydroxylamines
19-58 Reduction of nitro or nitroso compounds; reaction between nitroso compounds and hydroxylamines

Benzoins *(see* Hydroxy Aldehydes and Ketones)

Bisamides

14-15 Coupling of amides
16-12 Addition of amides to aldehydes or ketones
16-13 Addition of amides to aldehydes

16-66 Reaction between isocyanides, acids, amines, and aldehydes or ketones (Ugi)

Bisulfite Addition Compounds (see Hydroxy Sulfonic Acids)

Boranes

12-33 Reaction between boron halides and Grignard reagents
15-16 Hydroboration of alkenes or alkynes
15-25 Reaction of borinates with organometallic compounds
17-14 Exchange reaction between boranes and alkenes
18-11 Migration of boron

Bunte Salts

10-41 Reaction between alkyl halides and thiosulfate ion

Carbamates

10-26 Reaction between K_2CO_3, amines, and halides
10-55 Reaction between chloroformates and primary amines
10-66 Reaction between alkyl halides, ethanol, and thiocyanate ion
10-75 Cleavage of tertiary amines with ClCOOPh
12-12 Insertion by nitrenes
12-53 Carbonylation of amines or nitro or nitroso compounds
16-7 Addition of alcohols to isocyanates
16-8 Reaction of alcohols with ClCN
18-13 Reaction between amides, bromine, and alkoxides (Hofmann), and similar rearrangement reactions
18-14 Rearrangement of acyl azides in the presence of alcohols (Curtius)

Carbodiimides

16-59 Addition of isocyanates to isocyanates

Carbonates

10-21 Alcoholysis of phosgene
10-26 Reaction between alkyl halides and carbonate salts

Carboxylic Acids

10-3 Hydrolysis of 1,1,1-trihalides
10-6 Hydrolysis of ortho esters
10-8 Hydrolysis of acyl halides

10-9	Hydrolysis of anhydrides
10-10	Hydrolysis of carboxylic esters
10-11	Hydrolysis of amides
10-73	Cleavage of carboxylic esters with LiI
10-86	Reductive cleavage of carboxylic esters
10-104	Malonic ester synthesis
10-106	Alkylation of carboxylate ions
10-108	Hydrolysis of oxazines
10-113	Carbonylation of alkyl halides and other substrates
11-19	Carboxylation of aromatic rings with carbonyl halides
11-20	Carboxylation of aromatic rings with carbon dioxide (Kolbe–Schmitt)
11-38	Rearrangement of aromatic carboxylate ions
12-38	Decarboxylation of dicarboxylic acids
12-41	Basic cleavage of P-keto esters or p-diketones
12-42	The haloform reaction
12-43	Cleavage of nonenolizable ketones
13-13	Carboxylation of aryl halides
13-21	Rearrangement of aromatic nitro compounds upon treatment with cyanide ion (von Richter)
14-6	Oxidation of aldehydes
14-30	Reaction of diazonium fluoroborates with CO
15-3	Addition of water to ketenes
15-16	Oxidation of 1,1-diboranes
15-18	Addition of carbocations to 1,1-dichloroethene; addition of carboxylates to alkenes
15-24	Addition of alkylcopper reagents to unsaturated carboxylic acids
15-28	Free-radical addition of acids to alkenes
15-30	Hydrocarboxylation of alkenes
16-3	Hydrolysis of primary nitro compounds
16-4	Hydrolysis of nitriles
16-34	Addition of Grignard reagents to carbon dioxide
16-41	Reaction of ketones with tosylmethyl azide, followed by hydrolysis
16-47	Reaction of phosphoranes with CO_2
16-48	Tebbe, Petasis and alternative alkenylations
17-3	Pyrolysis of carboxylic esters
17-31	Fragmentation of certain ketoximes
18-7	Rearrangement of α-halo ketones (Favorskii)
18-8	Rearrangement of diazo ketones (Arndt–Eistert)
18-19	Oxidation of aldehydes
18-24	From boranes
19-7	Oxidative cleavage of α-diketones and α-keto acids
19-8	Oxidative cleavage of ketones and secondary alcohols
19-9	Oxidation of ozonides; ozonolysis of alkynes
19-10	Oxidative cleavage of alkenes, terminal alkynes, or aromatic rings

19-11 Oxidation of aromatic side chains
19-20 Oxidation of amines
19-21 Oxidation of primary alcohols or ethers
19-22 Oxidation of arylthioalkynes
19-60 Reaction between aldehydes and base (Cannizzaro)
19-63 Oxidation of aryl ketones by ammonium polysulfide (Willgerodt)

Carboxylic Esters *{see also* Dicarbonyl Compounds, Unsaturated Esters, etc.)

10-3 Alcoholysis of trihalides
10-6 Hydrolysis of ortho esters
10-21 Alcoholysis of acyl halides
10-22 Alcoholysis of anhydrides
10-23 Esterification of carboxylic acids
10-24 Transesterification
10-25 Alcoholysis of Amides and Hydrazides
10-26 Alkylation of carboxylic acid salts
10-27 Cleavage of ethers with anhydrides
10-28 Alkylation of carboxylic acids with diazo compounds
10-105 Alkylation of carboxylic esters
10-107 Alkylation of aryl esters
10-108 Alkylation and alcoholysis of oxazines
10-109 Reaction of halo esters or diazo esters with boranes
10-113 Carbonylation of alkyl halides and other substrates
10-114 Reaction between Grignard reagents and chloroformates
12-30 Carbonylation of organometallic compounds
12-41 Base cleavage of β-keto esters
12-42 Haloform cleavage of methyl ketones
13-3 Reaction between aryl halides and carboxylic acid salts
13-12 Arylation of carboxylic esters
13-13 Carbalkoxylation of aryl halides and phenols
13-15 Vicarious substitution of aryl nitro compounds
14-10 Free-radical acyloxylation
14-23 Carbalkoxylation of nitrogen heterocycles
14-37 Reaction between silver salts and iodine (Simonini)
15-4 Hydration of acetylenic ethers
15-5 Addition of alcohols or phenols to ketenes
15-6 Addition of carboxylic acids or acyl peroxides to alkenes
15-13 Selective reduction of conjugated esters
15-21 Addition of carboxylic esters to activated alkenes (Michael)
15-24 Addition of organometallic compounds to unsaturated esters
15-26 Addition of tin and mercury hydrides to unsaturated ketones
15-28 Free-radical addition of carboxylic esters to alkenes
15-30 Hydrocarboxylation of alkenes in the presence of alcohols
15-46 Addition of carboxylic acid salts to alkenes

15-54	Addition of OAc and SR to double bonds
16-6	Reductive acylation of ketones
16-8	Alcoholysis of nitriles
18-7	Rearrangement of α-halo ketones (Favorskii)
18-8	Rearrangement of diazo ketones in the presence of alcohols (Arndt-Eistert)
18-19	Reaction between ketones and peroxy compounds (Baeyer-Villiger)
19-8	Cleavage of cyclic ketones with NOCl and an alcohol
19-9	From ozonides
19-10	Oxidative cleavage of enol ethers
19-12	Reaction between carboxylic acids and lead tetraacetate
19-17	Oxidation of ethers
19-21	Oxidation of primary alcohols or aldehydes
19-22	Oxidation of enol ethers
19-61	Reaction between aldehydes and aluminum ethoxide (Tishchenko)
19-63	Reaction of acetophenones with $AgNO_3$–I_2 or other reagents

Catenanes

19-57	Acyloin condensation or other methods

Cyanamides

10-76	Cleavage of tertiary amines with cyanogen bromide (von Braun)
17-32	Dehydration of disubstituted ureas

Cyanates

10-12	Reaction of aroxides and cyanogen halides

Cyanoamines

10-46	Amination of cyanohydrins
11-28	Cyanation of aromatic amines
12-16	Cyanation of secondary amines
16-15	Reaction between aldehydes, ammonia, and nitriles (Mannich)
16-51	Addition of cyanide and ammonium ions to aldehydes or ketones (Strecker)
16-52	Addition of HCN to C=N or C≡N bonds

Cyano Carbonyl Compounds

10-104	Akylation of cyano carbonyl compounds
10-117	Acylation of nitriles by acyl halides
10-119	Acylation of nitriles by carboxylic esters

10-121	Reaction between acyl halides and CuCN
12-16	Cyanation of ketones
12-18	Cyanoethylation of enamines; reaction of enamines with cyanogen chloride
13-12	Arylation of cyano carbonyl compounds
15-21	Addition of alkenes (Michael)
15-27	Acylation of unsaturated nitriles
15-33	Addition of HCN to unsaturated aldehydes, ketones, or carboxylic esters
16-41	Addition of cyano carbonyl compounds to aldehydes or ketones (Knoevenagel)
16-49	Condensation of nitriles (Thorpe)
19-30	Dimerization of cyano carbonyl compounds

Cyanohydrins *(see* Hydroxy Nitriles)

Cycloalkanes and Alkenes *(see* Alicyclic Compounds)

Dialdehydes *(see* Dicarbonyl Compounds)

Diamines

10-52	Reacation of amines with aziridines
15-52	Diamination (additon of nitrogen, nitrogen)
19-55	Dimerizatino of imines

Diazo Compounds

10-122	Reaction between acyl halides and diazomethane
12-9	Reaction of active hydrogen compounds with tosyl azide
12-47	Diazotization of α-amino esters and similar compounds
16-41	Addition of diazo esters to aldehydes
17-45	Elimination from N-nitroso-N-alkyl compounds
19-6	Oxidation of hydrazones

Diazonium Salts

11-5	Direct diazotization of aromatic rings
12-47	Diazotization of primary amines

1,2-Dicarbonyl Compounds

10-113	Dicarbonylation of halides
10-116	Dimerization of acyl halides
10-119	Acylation of 1,3-dithianes, followed by hydrolysis
16-27	Addition of RLi and CO to carboxylic esters

16-67 Reaction of metalated aldimines with CO_2
19-9 Ozonization of alkynes or aromatic rings
19-14 Oxidation of ketones with selenium dioxide
19-20 Oxidative cleavage of α-amino ketones
19-22 Oxidation of alkenes
19-26 Oxidation of alkynes
19-57 Reductive condensation of aromatic carboxylic acids

1,3-Dicarbonyl Compounds

10-104 Alkylation at a carbon bearing an active hydrogen
10-117 Acylation at a carbon bearing an active hydrogen
10-118 Acylation of carboxylic esters by carboxylic esters (Claisen; Dieckmann)
10-119 Acylation of ketones by carboxylic esters
10-120 Acylation of carboxylic acid salts
11-22 Reaction between aromatic compounds and diethyl oxomalonate
12-14 Acylation of acetals or ketals followed by hydrolysis
12-15 Alkoxycarbonylalkylation of aldehydes
12-18 Acylation of enamines followed by hydrolysis (Stork)
13-12 Arylation at a carbon bearing an active hydrogen
15-3 Cleavage of activated alkenes with water
15-21 Addition of active hydrogen compounds to alkenes (Michael)
15-28 Free-radical addition of 1,3-dicarbonyl compounds to alkenes
16-31 Reaction between nitriles, zinc, and α-halo esters (Blaise)
16-41 Addition of 1,3-dicarbonyl compounds to aldehydes or ketones (Knoevenagel)
16-43 Carboxylation of ketones and carboxylic esters
18-2 Rearrangement of epoxy ketones
18-9 Reaction of ketones with ethyl diazoacetate
19-14 Remote oxidation of ketones
19-30 Dimerization of β-keto esters or similar compounds

1,4-Dicarbonyl Compounds

10-6 Cleavage of furans
11-14 Acylation of aromatic rings by succinic anhydride
14-15 Coupling of ketones, carboxylic acids, and esters
15-27 Acylation of unsaturated ketones or alkynes
19-14 Remote oxidation of ketones
19-31 Dimerization of silyl enol ethers or of lithium enolates

1,5-Dicarbonyl Compounds

15-21 Addition of silyl enol ethers or silyl ketene acetals to unsaturated ketones or esters

Dicarboxylic Acids *{see* Dicarbonyl Compounds, Carboxylic Acids)

Dicyano Compounds

10-104	Alkylation of malononitriles
13-12	Arylation of malononitriles
15-21	Addition of nitriles to unsaturated nitriles (Michael)
15-33	Addition of HCN to triple bonds
16-41	Addition of malononitriles to aldehydes or ketones (Knoevenagel)
16-52	Addition of HCN to nitriles
19-10	Oxidation of *o*-diamines

Dienes

10-94	Coupling of vinylic halides with copper
10-97	Coupling of allylic halides with thioether anions
14-20	Arylation and alkylation of alkenes by vinyltin compounds (the Stille reaction)
14-32	Coupling of vinylic boranes
15-14	Hydrogenation of aromatic compounds
15-19	Coupling of alkynes
18-32	Sigmatropic rearrangments of 1,5-dienes (the Cope rearrangement)

Diesters *{see* Dicarbonyl Compounds)

Dihalides and Polyhalides

10-72	Treatment of epoxides with $SOCl_2$, Ph_3P and CCl_4 or Ph_3PCl_2
10-79	Reduction of trihalides
10-94	Coupling of halides with trihalides
12-38	Decarboxylation of trihalo acids
12-42	The haloform reaction
13-15	Vicarious substitution of aryl nitro compounds
14-1	Free-radical halogenation
15-2	Addition of hydrogen halides to alkynes
15-37	Addition of halogens to alkenes or alkynes
15-44	Free-radical addition of polyhalides to alkenes
16-22	Reaction of PCl_5, SF_4, or other reagents with aldehydes, ketones, or other C=O compounds
19-20	Treatment of amines with CuX and alkyl nitrites

Diketones *{see* Dicarbonyl Compounds)

Dinitro Compounds

14-12	Nitration of alkanes or nitro compounds

gem-Diols (Hydrates)

16-1 Hydration of aldehydes

1,2-Diols

10-7 Hydrolysis of epoxides
14-15 Coupling of alcohols
15-46 Hydroxylation of alkenes
16-27 Addition of a masked Grignard reagent to an aldehyde or ketone
16-41 From aromatic aldehydes and carbanions
19-55 Bimolecular reduction of aldehydes or ketones

1,3-Diols

16-46 Condensation between formaldehyde and aldehydes or ketones (Tollens)
16-53 Addition of aldehydes to alkenes (Prins)

Disulfides

10-40 Reaction between alkyl halides and disulfide ion
13-4 Reaction between aryl halides and disulfide ion
13-24 The Smiles rearrangement
15-40 Addition of ArSSCl to alkenes
19-32 Oxidation of thiols
19-47 Reduction of sulfonyl halides

Dithioacetals

10-38 From *gem*-dihalides or acetals and thiolate ions
15-7 Addition of thiols to alkynes
16-10 Addition of thiols to aldehydes or ketones

Dithiols

15-50 Reaction of alkenes with a disulfide and BF_3 etherate
16-10 Addition of H_2S to carbonyl compounds or imines

Enamines

10-107 Alkylation of enamines
15-8 Addition of amines to triple-bond compounds
16-12 Addition of amines to aldehydes or ketones
16-33 Reaction between Grignard reagents and formamides
16-47 Reaction of phosphonates with aldehydes or ketones

16-48 Tebbe, Petasis and alternative alkenylations
19-2 Dehydrogenation of tertiary amines

Enolate Ions

10-105 From enol acetates
12-3 Treatment of aldehydes or ketones with base
12-21 Treatment of active hydrogen compounds with base

Enol Carbamates

15-6 Reaction between alkynes, CO, and an amine

Enol Ethers and Esters

10-15 O-Alkylation of carbonyl compounds with diazo alkanes
10-17 Transetherification
10-21 Reaction between acyl halides and active hydrogen compounds
10-24 Transesterification
10-26 Acylation of vinylic halides
10-104 Alkylation with ortho esters
10-117 O-Acylation of 1,3-dicarbonyl compounds
15-5 Addition of alcohols or phenols to alkynes; addition of aldehydes or ketones to ketene
15-6 Addition of carboxylic acids to alkynes
16-5 Addition of alcohols or anhydrides to aldehydes or ketones
16-48 Reaction between carboxylic esters and Tebbe's reagent or metal carbene complexes
16-47 Reaction of α-alkoxy phosphoranes with aldehydes or ketones
16-48 Tebbe, Petasis, and alternative alkenylations
17-2 Cleavage of acetals
17-24 Elimination from β-halo acetals

Enols *{see* Unsaturated Alcohols and Phenols)

Enol Thioethers

15-7 Addition of thiols to alkynes
16-10 Reaction of aldehydes or ketones with thiols
19-2 Dehydrogenation and reduction of sulfoxides

Enynes

15-19 Dimerization of alkynes

Episulfides

10-38	Reaction between epoxides and phosphine sulfides
15-40	Cyclization of β-halo disulfides
16-62	Reaction of diazoalkanes with sulfur or thioketones

Epoxides

10-13	Cyclization of halohydrins
10-16	Cyclization of 1,2-diols
10-18	Payne rearrangement of 2,3-epoxy alcohols
14-7	Epoxidation of a secododecahedrane
15-48	Epoxidation of alkenes
16-27	Reaction of carbonyl compounds with *gem*-dihalides and Li or BuLi
16-45	Condensation between aldehydes and α-halo esters, ketones, or amides (Darzens)
16-61	Addition of sulfur ylids or diazomethane to aldehydes or ketones
19-63	Bimolecular reduction of aldehydes or ketones

Esters *{see* Carboxylic Esters, Inorganic Esters)

Ethers *{see also* Hydroxy Ethers, etc.)

10-6	Cleavage of oxonium ions
10-10	Reaction between carboxylic esters and alkoxide ion
10-12	Reaction between alkoxides or aroxides and alkyl halides (Williamson)
10-14	Reaction between alkoxides or aroxides and inorganic esters
10-15	Alkylation of alcohols or phenols with diazo compounds
10-16	Dehydration of alcohols
10-17	Transetherification
10-19	Alkylation of alcohols with onium salts
10-31	Exchange of ethers and oxonium salts
10-71	Cleavage of oxonium salts
10-84	Reduction of acetals or ketals
10-101	Reaction between Grignard reagents and acetals or ketals; dimerization of acetals
12-22	Reaction between Grignard reagents and terf-butyl peroxy esters
13-3	Reaction between aryl halides and alkoxides or aroxides
14-7	Cyclization of alcohols with lead tetraacetate
14-34	Desulfurization of thiono esters
15-7	Addition of alcohols or phenols to alkenes
15-28	Free-radical addition of ethers to alkenes
15-59	Heteroatom Diels–Alder reaction of ketones and aldhydes
16-6	Reductive alkylation of alcohols
19-36	Reduction of carboxylic esters

Glycidic Esters

15-34 Epoxidation of α,β-unsaturated esters
16-45 Condensation between aldehydes or ketones and α-halo esters (Darzens)

Grignard Reagents *(see* Organometallic Compounds)

Halo Acids, Esters, Aldehydes, Ketones *(see* Halo Carbonyl Compounds)

Haloamines

15-41 Addition of N-haloamines to unsaturated compounds

N-Haloamines and Amides

12-52 Halogenation of amines or amides

Halo Carbonyl Compounds

10-72 Reaction of acyl chlorides with ethylene oxide and NaI
10-74 Reaction of diazo ketones with hydrohalic acids
12-4 Halogenation of aldehydes or ketones
12-5 Halogenation of carboxylic acids (Hell–Volhard–Zelinskii) and acid derivatives
15-37 Addition of halogens to ketenes
15-39 Addition of HOBr or HOCl to triple bonds; addition of chlorine acetate or other reagents to alkenes
15-45 Addition of acyl halides to alkenes
18-10 Rearrangement of halo epoxides
19-22 Oxidation of certain alkenes

Halo Ethers and Acetals

15-39 Addition of hypohalites to double bonds
16-22 Reaction of carboxylic esters with C1F or other reagents

Haloformic Esters

10-21 Alcoholysis of phosgene

Halohydrins

10-72 Cleavage of epoxides with hydrogen halides
15-39 Addition of hypohalous acids to alkenes

Halo Sulfides, Sulfoxides, and Sulfones

12-6 Halogenation of sulfoxides and sulfones
15-41 Addition of sulfonyl halides to alkenes
19-62 Pummerer rearrangements

Hemiacetals

14-4 Electrolytic oxidation of tetrahydrofuran
16-5 Addition of alcohols to aldehydes or ketones

Hemiaminals

16-12 Reaction between aldehydes or ketones and amines

Hemimercaptals

16-10 Addition of thiols to aldehydes or ketones

Heterocyclic Compounds *{see also* Anhydrides, Aziridines, Epoxides, Episulfides, Imides, Lactams, Lactones)

10-13 Cyclization of halohydrins (cyclic ethers)
10-16 Cyclization of glycols (cyclic ethers; furans)
10-17 Reaction of diols with acetals (cyclic acetals)
10-38 Reaction of dihalides with sulfide ion (cyclic sulfides)
10-44 Cyclization of haloamines (cyclic amines); dealkylation of quaternary salts of nitrogen heterocycles
10-62 Reaction between ureas and malonic esters (cyclic ureides)
11-9 Sulfurization of aromatic rings (cyclic sulfides)
11-14 Intramolecular acylation
11-21 Intramolecular amidation of aromatic rings
11-23 Cyclization of amides with $POCl_3$ (isoquinolines)
12-12 Intramolecular nitrene insertion
13-5 Intramolecular arylation of amines (cyclic amines)
13-12 Intramolecular arylation of active hydrogen compounds
13-15 Arylation of heterocyclic nitrogen compounds
13-16 Amination of heterocyclic nitrogen compounds
14-7 Cyclization of alcohols with lead tetraacetate (tetrahydrofurans)
14-14 Cyclization of N-tosyl malonic esters
14-17 Intramolecular arylation (Pschorr)
14-23 Alkylation, arylation, and carbalkoxylation of nitrogen heterocycles
15-8 Addition of ammonia or primary amines to conjugated diynes (pyrroles)
15-14 Hydrogenation of heterocyclic aromatic rings

15-16 Addition of boranes to dienes (cyclic boranes)
15-49 Photooxidation of dienes (cyclic peroxides)
15-50 Cyclization of unsaturated alcohols with sulfenyl chlorides (tetrahydrofurans)
15-53 Addition of aminonitrenes to triple bonds (1-azirines)
15-57 1,3-Dipolar addition to double or triple bonds
15-58 Diels–Alder addition involving hetero atoms
15-59 Heteroatom Diels-Alder reactions
15-62 Expansion of heterocyclic rings upon treatment with carbenes
15-64 Other cycloaddition reactions
16-5 Formation of cyclic acetals; reaction between diketones and acids (furans, pyrans)
16-10 Addition of H_2S to aldehydes or ketones (cyclic thioacetals)
16-12 Reaction between aldehydes and ammonia (cyclic amines)
16-12 Intramolecular addition of amines to carbonyl groups (cyclic imines)
16-17 Reaction of dinitriles with ammonia (cyclic imidines)
16-19 Reaction between hydrazines and P-diketones or β-keto esters (pyrazoles; pyrazolones)
16-41 Reaction of ketones with tosylmethylisocyanide (oxazolines)
16-53 Reaction between alcohols and aldehydes (dioxanes)
16-58 Trimerization of aldehydes (trioxanes)
16-63 Addition of alkenes to aldehydes or ketones (oxetanes)
17-20 Reaction of dichlorobenzyl sulfones with base (thiiren-1,1-dioxides)
17-37 Extrustion of CO_2 from benzoxadiazepinones (indazoles)
17-40 Condensation of thiobenzilic acid with aldehydes or ketones (oxathiolan-5-ones)
18-14 Curtius rearrangement of cycloalkyl or aryl azides
18-18 Rearrangement of N-haloamines (cyclic amines)
18-21 Ring enlargement of cyclic quaternary ammonium salts (cyclic amines)
18-31 Ring expansion of N-acylaziridines (oxazoles)
18-34 Cyclization of arylhydrazones (Fischer indole synthesis)
18-40 Acid-catalyzed rearrangement of N-haloamines (pyrrolidines; piperidines Hofmann–Löffler)
19-1 Aromatization of heterocyclic rings
19-33 Reduction of α,β-unsaturated ketones (pyrazolones)
19-35 Reduction of lactams (cyclic amines)
19-36 Reduction of lactones (cyclic ethers)

Hydrates *(see* gem-Diols)

Hydrazides

10-55 Acylation of hydrazines with acyl halides
10-58 Acylation of hydrazines with carboxylic esters

Hydrazines

13-16	Hydrazination of heterocyclic nitrogen compounds
15-8	Addition of hydrazines to alkenes
18-18	Reaction between ureas and NaOBr (Hofmann)
19-41	Reduction of N-nitro compounds
19-43	Reduction of N-nitroso compounds
19-46	Reduction of azo compounds or diazonium salts

Hydrazo Compounds (see Hydrazines)

Hydrazones

12-7	Aliphatic diazonium coupling
16-19	Addition of hydrazines to aldehydes or ketones

Hydroperoxides

10-32	Reaction between alkyl or acyl halides and hydrogen peroxide
12-24	Reaction between organometallic reagents and oxygen
14-8	Autoxidation; reaction of alkenes with singlet oxygen

Hydroxamic Acids

10-55	Acylation of hydroxylamine with acyl halides
10-58	Acylation of hydroxylamine with carboxylic esters
16-3	Hydrolysis of aliphatic nitro compounds

Hydroxy Acids

10-10	Hydrolysis of lactones
10-113	Dicarbonylation of aryl iodides
11-20	Carboxylation of phenols
11-22	Reaction between aromatic compounds and diethyl oxomalonate
12-25	Oxidation of dilithiated carboxylic acids
16-4	Hydrolysis of cyanohydrins
16-31	Reaction between aldehydes or ketones and zinc carboxylates
16-41	Addition of dianions of carboxylic acids to ketones
18-6	Rearrangement of benzils
18-7	Rearrangement of α,β-epoxy ketones (Favorskii)
19-60	Reaction between keto aldehydes and base

Hydroxy Aldehydes and Ketones

10-5	Hydrolysis of diazo ketones
10-107	Reaction between dithiane salts and epoxides

10-108 Alkylation of oxazines with epoxides
11-30 Rearrangement of phenolic esters (Fries)
12-18 Alkylation of enamines with epoxides
14-4 Hydroxylation of ketones
16-23 Monoreduction of α-diketones
16-27 Addition of RLi and CO to ketones
16-31 Reaction between aldehydes or ketones, zinc, and halo ketones
16-38 Combination of aldehydes and/or ketones (aldol)
16-39 Mukaiyama aldol reactions
16-41 Various Knoevenagel methods
16-46 Condensation of formaldehyde with aldehydes or ketones (Tollens)
16-54 Condensation of aromatic aldehydes (benzoin)
16-67 Reaction of metalated aldimines with aldehydes or epoxides
18-1 Rearrangement of epoxy silyl ethers
18-4 Rearrangement of α-hydroxy aldehydes or ketones
19-15 Oxidation of methylene to OH, O_2CR, or OR
19-19 Oxidation of epoxides
19-22 Oxidation of alkenes
19-57 Condensation of carboxylic esters (acyloin)

Hydroxyamines and Amides

10-50 Animation of epoxides
10-51 Reaction of amines with oxetanes
10-54 Hydrolysis of silyloxy isocyanides
11-22 Hydroxymethylation of aromatic amines
11-25 Aminoalkylation and amidoalkylation of phenols
11-29 Hydroxylation of amines
13-23 Rearrangement of aryl hydroxylamines (Bamberger)
14-4 Hydroxylation of amides
15-51 Oxyamination of double bonds; aminomercuration of alkenes, followed by hydrolysis
16-12 Addition of ammonia, amines or amides to aldehydes or ketones
16-13 Addition of amides to aldehydes
16-31 Reaction between aldehydes or ketones, zinc, and halo amides
16-41 Reaction of aldehydes with the conjugate base of formamide; reaction of ketones with imines
16-66 Reaction between isocyanides, $TiCl_4$ and aldehydes or ketones, followed by hydrolysis
19-55 Coupling of ketones and O-methyl oximes

Hydroxy Esters

10-24 Transesterification of lactones
10-27 Acylation of epoxides
14-4 Hydroxylation of carboxylic esters

16-30 Addition of conjugated alkenes to aldehydes (the Baylis-Hillman reaction)
16-31 Reaction between aldehydes or ketones, zinc, and α-halo esters (Reformatsky)
16-40 Condensation between carboxylic esters and aldehydes or ketones
16-41 Addition of α-metalated esters to ketones
19-15 Oxidation of methylene to OH, O_2CR, or OR

Hydroxy Ethers

10-18 Alcoholysis of epoxides

Hydroxylamines

15-8 Addition of hydroxylamine to alkenes
16-24 Reduction of oximes
16-35 Addition of alkyllithium compounds to oximes
17-8 Cleavage of amine oxides (Cope)
18-21 Rearrangement of N-oxides (Meisenheimer)
19-23 Oxidation of amines
19-42 Reduction of nitro compounds

Hydroxy Nitriles

10-111 Reaction between epoxides and cyanide ion
14-4 Hydroxylation of nitriles
16-31 Reaction between aldehydes and ketones, zinc, and halo nitriles
16-41 Addition of nitriles to ketones
16-51 Addition of HCN to aldehydes or ketones

Hydroxy Sulfonic Acids

16-11 Addition of bisulfite ion to aldehydes or ketones

Hydroxy Thiols and Thioethers

10-37 Reaction between epoxides and NaSH
10-38 Reaction between epoxides and thiolate ions
11-26 Thioalkylation of phenols
15-50 Hydroxysulfenylation af alkenes
16-10 Addition of H_2S to aldehydes or ketones

Imides (including Ureides)

10-55 Reaction between acyl halides and lithium nitride
10-56 Amination of anhydrides

10-61 N-Alkylation of imides
10-62 N-Acylation of amides or imides
15-8 Addition of imides to alkenes
15-30 Hydrocarboxylation of unsaturated amides
18-13 Reaction between amides and NaOBr (Hofmann)
18-14 Rearrangement of acyl azides in the presence of water (Curtius)
19-17 Oxidation of lactams

Imines

12-8 Reaction between active hydrogen compounds and nitroso compounds
12-18 Treatment of enamines with nitrilium salts
15-8 Addition of amines to triple-bond compounds
15-59 Heteroatom Diels–Alder reaction of imines
16-12 Addition of ammonia, amines to aldehydes or ketones
16-37 Addition of Grignard reagents to nitriles
16-47 Addition of ylids to nitroso compounds
16-67 Reaction of isocyanides with organometallic compounds (metalated imines)
18-14 Pyrolysis of alkyl or aryl azides
18-17 Reaction between oxime sulfonates and organometallic compounds
18-18 Rearrangement of trityl N-haloamines and hydroxylamines (Stieglitz)
19-5 Dehydrogenation of secondary amines
19-44 Reduction of oximes

Imino Esters (Imidates), Imino Thioesters, and Their Salts

11-27 Reaction of phenols with nitriles
16-8 Alcoholysis of nitriles (Pinner)
18-17 Reaction between oxime sulfonates and organoaluminum sulfides
18-42 From amides

Imino Nitriles

18-17 Reaction between an oxime sulfonate, an organoaluminum compound, and Me_3SiCN

Inorganic Esters

10-33 Reaction of alcohols or alkyl halides with inorganic acids or halides
12-26 Oxidation of trialkylboranes
13-7 Reaction between aryl halides and $POCl_3$

13-17 Reaction between diazonium salts and F3CSO2OH
15-39 Addition of Cl_2 and SO_3 to alkenes

Isocyanates

10-55 Reaction between amines and phosgene
10-62 Reaction between oxalyl chloride and unsubstituted amides
10-66 Alkylation or acylation of cyanate ion
12-53 Carbonylation of amines
18-13 Reaction between amides and NaOBr (Hofmann)
18-14 Rearrangement of acyl azides (Curtius)
18-15 Rearrangement of hydroxamic acids (Lossen)
18-17 Addition of hydrazoic acid to carboxylic acids (Schmidt)

Isocyanides

10-54 Reaction between primary amines and chloroform, or Me_3SiCN and epoxides or oxetanes
10-111 Reaction between alkyl halides and cyanide ion
17-33 Elimination of water from N-alkylformamides
19-48 Reduction of isocyanates

Isothiocyanates

10-55 Reaction between amines and thiophosgene
10-66 Alkylation or acylation of thiocyanate ion
13-18 Reaction between diazonium salts and thiocyanate ion
16-18 Addition of amines to carbon disulfide

Isothiuronium Salts

10-37 Reaction between alkyl halides and thiourea

Ketals *(see* Acetals)

Ketenes

17-1 Pyrolysis of carboxylic acids
17-13 Dehydrohalogenation of acyl halides
17-23 Dehalogenation of α-halo acyl halides
18-8 Rearrangement of diazo ketones (Wolff)

Ketenimines

16-47 Reaction between phosphoranes and isocyanates
17-1 Dehydration of amides

Keto Acids, Aldehydes, and Esters *(see also* Dicarbonyl Compounds)

Ketones *(see also* Dicarbonyl Compounds, Unsaturated Carbonyl Compounds, etc.)

10-1	Hydrolysis of vinylic halides
10-2	Hydrolysis of *gem*-dihalides
10-4	Hydrolysis of enol esters of inorganic acids
10-6	Hydrolysis of enol ethers, ketals, thioketals, etc.
10-10	Hydrolysis of enol esters
10-79	Reduction of halo ketones
10-81	Reduction of hydroxy ketones
10-87	Reduction of diazo ketones or nitro ketones
10-94	Coupling of halo ketones with lithium alkylcopper reagents
10-104	Acetoacetic ester synthesis and similar reactions
10-105	Alkylation of ketones
10-107	Alkylation and hydrolysis of dithianes and similar compounds
10-108	Alkylation and hydrolysis of oxazines
10-109	Reaction of halo ketones or diazo ketones with boranes
10-112	Carbonylation of alkyl halides
10-114	Reaction between acyl halides and organometallic compounds
10-115	Reaction between other acid derivatives and organometallic compounds
10-117	Acylation of active hydrogen compounds followed by cleavage
10-119	Reduction of β-keto sulfoxides
10-120	Acylation of carboxylic acid salts followed by cleavage
10-123	Ketonic decarboxylation
11-14	Acylation of aromatic rings (Friedel-Crafts)
11-19	Reaction between aromatic rings and phosgene
11-27	Acylation of aromatic rings with nitriles (Hoesch)
11-30	Rearrangement of phenolic ethers (Fries)
11-35	Photolysis of acylated arylamines
12-2	Rearrangement of hydroxy alkenes
12-15	Reaction between aldehydes and boron-stabilized carbanions
12-18	Alkylation of enamines followed by hydrolysis (Stork)
12-24	Oxidation of *gem*-dimetallic compounds
12-30	Carbonylation of organometallic compounds
12-38	Decarboxylation of (3-keto acids or esters
12-39	Cleavage of tertiary alkoxides
12-40	Reaction between amino acids and anhydrides (Dakin-West)
12-41	Basic cleavage of (3-diketones
13-12	Arylation of ketones
13-13	Acylation of aryl iodides
14-19	Arylation of allylic alcohols
14-23	Acylation of nitrogen heterocycles

14-30	Reaction of diazonium salts with oximes, followed by hydrolysis; or with R_4Sn and CO; or with silyl enol ethers
15-4	Hydration of alkynes or allenes
15-13	Selective reduction of unsaturated ketones
15-14	Reduction of phenols
15-16	Oxidation of boranes; hydrolysis of unsaturated boranes
15-21	Addition of ketones to activated alkenes (Michael)
15-24	Addition of organometallic compounds to unsaturated ketones
15-25	Addition of boranes to unsaturated ketones
15-26	Addition of tin and mercury hydrides to unsaturated ketones
15-28	Free-radical addition of aldehydes or ketones to alkenes
15-29	Carbonylation of double And triple bonds in the presence of an alkene
15-31	Hydroacylation of alkenes
15-32	Addition of aldehydes to alkenes
15-62	Hydrolysis of bicyclo[4.1.0]heptanes
16-2	Hydrolysis of imines, oximes, hydrazones, and other C=N compounds
16-3	Hydrolysis of secondary aliphatic nitro compounds (Nef)
16-32	Reaction between lithium carboxylates and alkyllithium compounds
16-48	Indirectly, from carboxylic esters
16-37	Addition of Grignard reagents to nitriles
16-42	Hydrolysis of epoxy silanes
16-67	Reaction of alkyl halides with metalated aldimines
17-1	Dehydration of 1,2-diols
17-25	Fragmentation of y-amino or y-hydroxy halides
17-26	Fragmentation of 1,3-diols
17-31	Fragmentation of certain ketoximes
17-34	Pyrolysis of β-hydroxy alkenes
18-2	Rearrangement of glycols and related compounds (pinacol)
18-3	Ring expansion of certain hydroxyamines (Tiffeneu–Demyanov)
18-4	Acid-catalyzed ketone rearrangements
18-9	Homologation of aldehydes or ketones
18-13	Reaction between α-hydroxy or α-halo amides and NaOBr (Hofmann)
18-20	Cleavage of hydroperoxides
18-24	Treatment of boranes with CO and H_2O, followed by NaOH and H_2O_2; or with CN^- followed by trifluoroacetic anhydride; from dialkylchloroboranes
18-26	Treatment of lithium alkynyltrialkylborates with electrophiles
18-30	[1,3] Sigmatropic rearrangements of allylic vinylic ethers
19-3	Oxidation of secondary alcohols
19-7	Oxidative cleavage of glycols and related compounds
19-9	Ozonolysis of alkenes
19-10	Oxidative cleavage of alkenes

19-11	Oxidation of diarylmethanes
19-13	Bisdecarboxylation of malonic acids
19-14	Oxidation of activated or unactivated methylene groups
19-19	Oxidation of secondary alkyl halides and tosylates
19-20	Oxidation of amines or nitro compounds
19-22	Oxidation of alkenes with noble metal salts
19-33	Reduction of diketones or quinones
19-50	Indirect oxidative decyanation of nitriles

Lactams

10-57	Cyclization of amino acids
10-58	Reaction between lactones and ammonia or amines; ring expansion of lactams
10-61	Cyclization of halo amides
15-8	Addition of lactams to alkenes
15-30	Hydrocarboxylation of unsaturated amines
15-38	Halolactamization from alkene acids
16-32	Reaction between imines, zinc, and halo esters
16-47	Reaction between imides and phosphoranes
16-64	Addition of ketenes to imines; addition of enamines to isocyanates
18-16	Reaction between cyclic ketones and hydrazoic acid (Schmidt)
18-17	Rearrangement of oximes of cyclic ketones (Beckmann)
18-18	Expansion of aminocyclopropanols
19-17	Oxidation of cyclic tertiary amines

Lactones

10-23	Cyclization of hydroxy acids
10-26	Cyclization of halo acids
10-98	Intramolecular coupling
12-41	Cleavage of cyclic α-cyano ketones
15-5	Internal addition of alcohols to a ketene function
15-6	Cyclization of alkeneic acids
15-30	Hydrocarboxylation of unsaturated alcohols
15-38	Halolactonization from alkene acids
15-56	Reaction of alkenes with manganese(III) acetate
16-47	Reaction of anhydrides with phosphoranes
16-63	Addition of ketenes to aldehydes or ketones
17-37	Extrusion of CO_2 from 1,2-dioxolane-3,5-diones
17-39	Decarboxylation of cyclic peroxides (Story)
18-19	Reaction between cyclic ketones and peroxy compounds (Baeyer-Villiger)
18-40	Rearrangement of N-halo amides
19-17	Oxidation of cyclic ethers

19-21 Oxidation of diols
19-37 Reduction of cyclic anhydrides
19-60 Oxidative–reductive ring closure of dialdehydes

Mercaptals *(see* Thioacetals)

Mercaptans *(see* Thiols)

Metallocenes

12-33 Reaction between sodium cyclopentadienylid and metal halides

Monoesters of Dicarboxylic Acids

10-22 Alcoholysis of cyclic anhydrides
10-24 Equilibration of dicarboxylic acids and esters
16-8 Alcoholysis of cyano acids
19-10 Oxidative cleavage of catechols

Nitriles *(see also* Dicyano Compounds, Cyano Carbonyl Compounds, etc.)

10-105 Alkylation of nitriles
10-109 Reaction of halo nitriles or diazo nitriles with boranes
10-111 Reaction between alkyl halides and cyanide ion
11-28 Cyanation of aromatic rings
12-16 Cyanation of ketones, nitro compounds, or benzylic compounds
12-31 Cyanation of organometallic compounds
12-38 Decarboxylation of α-cyano acids
13-10 Reaction between aryl halides and CuCN (Rosenmund-von Braun)
13-12 Arylation of nitriles
13-15 Vicarious substitution of aryl nitro compounds
14-25 Reaction between diazonium salts and CuCN (Sandmeyer)
14-37 Reaction of acyl peroxides with copper cyanide
14-39 Decarbonylation of aromatic acyl cyanides
15-13 Selective reduction of unsaturated nitriles
15-21 Addition to activated alkenes (Michael)
15-25 Addition of boranes to acrylonitrile
15-26 Addition of tin and mercury hydrides to unsaturated nitriles
15-28 Free-radical addition of nitriles to alkenes
15-33 Addition of HCN to alkenes
15-54 Addition of CN and SR to double bonds
16-21 From aldehydes or carboxylic esters
16-41 Reaction of ketones with tosylmethylisocyanide

16-52 Addition of KCN to sulfonyl hydrazones
16-60 Reaction between acid salts and BrCN
17-30 Dehydration of aldoximes and similar compounds
17-31 Fragmentation of ketoximes
17-32 Dehydration of amides
18-21 Rearrangement of isocyanides
19-5 Dehydrogenation of amines
19-6 Oxidation of hydrazones
19-12 Treatment of carboxylic acids with trifluoroacetic anhydride and $NaNO_2$
19-48 Reduction of nitrile oxides
19-51 Reduction of nitro compounds with $NaBH_2S_3$

Nitro Compounds

10-64 Reaction between alkyl halides and nitrite ion
10-104 Alkylation of nitro compounds
11-2 Nitration of aromatic rings
11-31 Rearrangement of N-nitro aromatic amines
12-38 Decarboxylation of α-nitro acids
12-49 N-Nitration of amines or amides
13-15 Alkylation of aromatic nitro compounds
14-12 Nitration of alkanes
14-26 Reaction between diazonium salts and sodium nitrite
15-8 Nitromercuration-reduction of alkenes
15-13 Reduction of unsaturated nitro compounds
15-21 Addition to activated alkenes (Michael)
15-24 Addition of organometallic reagents to nitroalkenes
15-42 Addition of NOCl and other nitrogen compounds to alkenes
15-54 Addition of NO_2 and SR to double bonds
16-41 Addition of nitro compounds to aldehydes or ketones; reaction of pyrylium salts with nitromethane
16-43 Carboxylation of nitro compounds
19-1 Oxidation of primary amines, oximes, azides, isocyanates, or nitroso compounds

Nitrogen Ylids

12-20 Treatment of quaternary ammonium salts with organometallic compounds

Nitrones

10-36 Alkylation of oximes

Nitroso Compounds

11-3	Nitrosation of aromatic rings
11-32	Rearrangement of N-nitroso aromatic amines (Fischer-Hepp)
11-38	Nitrosative decarboxylation of aromatic acids
12-8	Nitrosation at a carbon bearing an active hydrogen
12-49	Reaction between secondary amines or amides and nitrous acid
15-42	Addition of NOCl to alkenes
18-40	Photolysis of nitrites (Barton)
19-6	Oxidation of hydroxylamines
19-23	Oxidation of primary amines

Olefins *(see* Alkenes)

Organometallic Compounds *(see also* Boranes)

11-38	Replacement of aromatic COOH with Hg
12-20	Metallation of susceptible positions with organometallic compounds
12-21	Metallation of susceptible positions with metals or strong bases
12-23	Cleavage of alkyl groups from di- or polyvalent organometallic compounds
12-32	Reaction between an organometallic compound and a metal
12-33	Reaction between an organometallic compound and a metal halide
12-34	Reaction between an organometallic compound and an organometallic compound (exchange)
12-36	Metallation of alkyl or aryl halides with metals
12-36	Rearrangement of Grignard reagents
12-37	Metallation of alkyl or aryl halides with organometallic compounds
12-38	Decarboxylation of carboxylic acid salts
14-35	Reaction between sulfides and lithium or lithium naphthalide
15-17	Hydrometallation of alkenes
15-24	Reaction between copper-containing compounds and organolithium compounds
15-23	Addition of allylic zinc compounds to vinylic Grignard and lithium reagents (*gem*-dimetallic compounds)

Ortho Esters

10-12	Reaction of alkoxides with 1,1,1-trihalides (Williamson)
10-17	Transetherification
16-5	Addition of alcohols to formic acid

Osazones

16-19	Addition of hydrazines to α-hydroxy aldehydes or ketones

Oxime Ethers

10-15 Alkylation of oximes with diazo compounds
10-36 Alkylation of oximes with alkyl sulfates

Oximes

12-8 Nitrosation at a carbon bearing an active hydrogen
15-42 Addition of NOCl to alkenes
16-20 Addition of hydroxylamine to aldehydes or ketones
16-35 Addition of Grignard reagents to the conjugate bases of nitro compounds
18-40 Photolysis of nitrites (Barton)
19-8 Cleavage of cyclic ketones with NOCl and an alcohol
19-23 Oxidation of aliphatic primary amines
19-51 Reduction of nitro compounds

Oxiranes *{see* Epoxides)

Oxonium Salts

10-31 Reaction between alkyl halides and ethers or ketones

Ozonides

19-9 Ozonolysis of alkenes

Peptides

10-57 Coupling of amino acids

Peroxides *{see also* Hydroperoxides, Peroxy acids)

10-32 Reaction of alkyl and acyl halides with peroxide ion
14-9 Reaction between hydroperoxides and susceptible hydrocarbons
15-5 Oxymercuration-reduction of alkenes in the presence of a hydroperoxide
15-49 Photooxidation of dienes
17-39 Reaction of ketones with H_2O_2

Peroxy Acids

19-29 Oxidation of carboxylic acids

Phenols

10-10	Hydrolysis of phenolic esters
10-33	Cleavage of phenolic ethers with sulfonic acids
10-38	Cleavage of phenolic ethers
10-46	Cleavage of phenolic ethers
10-71	Cleavage of phenolic ethers with HI or HBr
11-29	Electrophilic hydroxylation of aromatic rings
11-30	Rearrangement of phenolic esters (Fries)
12-24	Oxidation of aryl organometallic compounds
13-1	Hydrolysis of aryl halides and other compounds
13-2	Alkali fusion of sulfonate ions
13-17	Hydrolysis of diazonium salts
13-23	Rearrangement of N-hydroxylamines
14-5	Free-radical hydroxylation of aromatic rings
14-21	Phenylation of phenols
15-62	Ortho methylation of phenols
16-23	Reduction of quinones
18-5	The dienone-phenol rearrangement
18-19	Cleavage of aryl ketones with peracids (Baeyer-Villiger)
18-20	Rearrangement of aralkyl peroxides
18-33	Rearrangement of allylic aryl ethers (Claisen)
18-43	Rearrangement of azoxy compounds (Wallach)
19-1	Aromatization of cyclic ketones
19-38	Reduction of phenolic esters
19-39	Reduction of certain acids and esters

Phosphines

10-44	Reaction between alkyl halides and phosphine
10-87	Reduction of quaternary phosphonium salts
12-33	Reaction between phosphorus halides and Grignard reagents

Phosphonates

16-47	Reaction between alkyl halides and phosphites (Arbuzov)

Phosphoranes

16-47	Treatment of phosphonium ions with alkyllithiums

Quaternary Ammonium and Phosphonium Salts

10-44	Alkylation of amines (Menschutkin) or phosphines
15-8	Addition of tertiary amines to alkenes

16-47 Reaction of phosphines with Michael alkenes or with alkyl halides

Quinones

11-14 Intramolecular Friedel-Crafts acylation of diaryl ketones
19-4 Oxidation of phenols or aromatic amines
19-18 Oxidation of aromatic hydrocarbons

Schiff Bases (see Imines)

Selenides

10-38 Selenylation of alkyl halides
12-13 Selenylation of aldehydes, ketones, and carboxylic esters
12-27 Selenylation of organometallic compounds
19-49 Reduction of selenoxides

Semicarbazones

16-19 Addition of semicarbizide to aldehydes or ketones

Silanes

10-20 Reaction of aryl silanes with fluoride
15-34 Addition of silanes to alkenes

Silyl Enol Ethers

12-22 Trialkylsilylation of ketones or aldehydes
12-25 Reaction betweeen vinylic lithium compounds and silyl peroxides
15-24 Michael-type reaction in the presence of Me_3SiCl

Sulfenyl Chlorides

14-11 Chlorosulfenation

Sulfides *{see* Thioethers)

Sulfinic Acids and Esters

10-128 Reduction of sulfonyl chlorides
12-27 Reaction of Grignard reagents with SO_2
13-24 The Smiles rearrangement
14-27 Reaction of diazonium salts with $FeSO_4$ and Cu
17-11 Cleavage of sulfones

Sulfonamides

10-61	N-Alkylation of sulfonamides
10-104	Alkylation of sulfonamides
10-109	Reaction of halo sulfonamides with boranes
10-126	Reaction between sulfonyl halides and ammonia or amines
13-15	Vicarious substitution of aryl nitro compounds
15-8	Addition of sulfonamides to alkenes
19-35	Reduction of acyl sulfonamides
19-46	Reduction of sulfonyl azides

Sulfones

10-42	Reaction between alkyl halides and sulfinates
10-104	Alkylation of sulfones
10-105	Alkylation of sulfones
10-109	Reaction of halo sulfones with boranes
10-119	Reaction between carboxylic esters and methylsulfonyl carbanion
10-129	Reaction between sulfonic acid derivatives and organometallic compounds
11-10	Sulfonylation of aromatic rings
13-4	Reaction between aryl halides and sulfinate ions
13-15	Vicarious substitution of aryl nitro compounds
15-21	Addition of sulfones to activated alkenes (Michael)
15-24	Addition of organometallic compounds to unsaturated sulfones
15-40	Addition of sulfonyl halides to alkenes
16-41	Addition of sulfones to aldehydes or ketones (Knoevenagel)
19-28	Oxidation of thioethers or sulfoxides

Sulfonic Acid Esters

10-33	Reaction between alcohols or ethers and sulfonic acids
10-104	Alkylation of sulfonic acid esters
10-105	Alkylation of sulfonic acid esters
10-109	Reaction of halo sulfonic acid esters with boranes
10-125	Alcoholysis of sulfonic acid derivatives
13-15	Vicarious substitution of aryl nitro compounds
16-41	Addition of sulfonic acid esters to aldehydes or ketones (Knovevenagel)

Sulfonic Acids

10-124	Hydrolysis of sulfonic acid derivatives
11-7	Sulfonation of aromatic rings
11-39	Sulfonation with rearrangement (Jacobsen)

13-4 Reaction between aryl halides and sulfite ion
19-25 Oxidation of thiols or other sulfur compounds

Sulfonium Salts

10-38 Reactions between alkyl halides and thioethers

Sulfonyl Azides

10-126 Reaction between sulfonyl halides and azide ion

Sulfonyl Halides

10-127 From sulfonic acids and derivatives
11-8 Halosulfonation of aromatic rings
12-27 Reaction of Grignard reagents with sulfuryl chloride or with SO_2 followed by X_2
14-11 Free-radical halosulfonation (Reed)
14-27 Reaction of diazonium salts with SO_2 and $CuCl_2$

Sulfoxides

10-104 Alkylation of sulfoxides
10-119 Reaction between carboxylic esters and methysulfinyl anion
11-9 Sulfurization of aromatic rings with thionyl chloride
12-27 Reaction of Grignard reagents with sulfinic esters
15-24 Addition of organometallic compounds to unsaturated sulfoxides
15-50 Treatment of alkenes with O_2 and RSH
16-41 Addition of sulfoxides to aldehydes or ketones (Knoevenagel)
19-28 Oxidation of thioethers
19-49 Indirectly, from sulfones

Thioamides

11-21 Amidation of aromatic rings with isothiocyanates
14-13 From thioaldehydes generated *in situ*
19-63 Reaction of ketones with sulfur and ammonia or amines

Thiocarbamates

16-4 Hydrolysis of thiocyanates
16-7 Addition of alcohols to isothiocyanates

Thiocyanates

10-43 Reaction between alkyl halides and thiocyanate ion
13-4 Reaction between aryl halides and thiocyanate ion

13-18 Reaction between diazonium salts and thiocyanate ion
14-37 Reaction between acyl peroxides and copper thiocyanate
15-40 Addition of halogen and SCN to alkenes

Thioethers

10-38 Reaction between alkyl halides and thiolate ions or Na_2S
10-107 Alkylation of thioethers
11-9 Sulfurization of aromatic rings
11-26 Thioalkylation of aromatic rings
12-13 Sulfenylation of ketones, carboxylic esters, and amides
12-27 Reaction between Grignard reagents and sulfur or disulfides
13-4 Reaction between aryl halides and thiolate ions
13-18 Reaction bewteen diazonium salts and thiolate ions or Na_2S
14-34 Reduction of dithioacetals
15-7 Addition of thiols to alkenes
15-40 Addition of sulfenyl chlorides to alkenes
15-54 Diarylamino-arylthio-addition to double bonds
15-59 Heteroatom Diels–Alder reaction of thioketones and thioaldehydes
16-10 Reductive alkylation of thiols
18-21 Rearrangement of sulfonium salts (Stevens)
18-35 [2,3] Sigmatropic rearrangements of sulfur ylids
19-36 Reduction of thiol esters
19-49 Reduction of sulfoxides or sulfones

Thiol Acids and Esters

10-38 Reaction between alcohols and thiol acids
10-39 Reaction between acid derivatives and thiols or H_2S
11-27 Reaction between aromatic rings and thiocyanates
15-4 Hydration of acetylenic thioethers
15-7 Addition of thiol acids to alkenes; addition of thiols to ketenes
15-30 Hydrocarboxylation of alkenes in the presence of thiols
16-10 From carboxylic acids, alcohols, and P_4S_{10}
16-34 Addition of Grignard reagents to carbon disulfide

Thiols

10-10 Hydrolysis of thiol esters
10-37 Reaction of alkyl halides with NaSH; cleavage of isothiuronium salts
11-9 Sulfurization of aromatic compounds (Herz)
12-27 Reaction between Grignard reagents and sulfur
13-4 Reaction between aryl halides and NaSH
13-18 Reaction between diazonium salts and NaSH
15-7 Addition of H_2S to alkenes

16-33 Addition of lithium dialkylcopper reagents to dithiocarboxylic esters
19-47 Reduction of sulfonic acids or sulfonyl halides
19-54 Reduction of disulfides

Thioketones

16-10 From ketones

Thiono Esters and Thioamides

16-10 From carboxylic esters or amides
16-64 Addition of imines to thioketenes (β-thiolactams)

Thioureas *(see* Ureas)

Triazenes

11-4 Reaction between aromatic amines and diazonium salts
12-49 Reaction between amines and diazonium salts

Unsaturated Acids, Esters, Aldehydes, Ketones *(see* Unsaturated Carbonyl Compounds)

Unsaturated Alcohols and Phenols

12-2 Isomerization of allylic alcohols (formation of enols)
14-4 Allylic hydroxylation
15-14 Selective reduction of α,β-unsaturated aldehydes or ketones
15-24 Addition of organometallic compounds to propargylic alcohols
16-23 Selective reduction of α,β-unsaturated aldehydes or ketones
16-28 Addition of vinylic or alkynyl organometallic compounds to aldehydes or ketones
16-29 Addition of trialkylallylsilanes to aldehydes and ketones
16-30 Addition of conjugated alkenes to aldehydes (the Baylis–Hillman reaction)
16-41 Condensation of alkyne salts with aldehydes or ketones
16-47 Reaction of certain ylids with aldehydes (scoopy reactions)
16-48 Tebbe, Petasis and alternative alkenylations
16-53 Addition of aldehydes to alkenes (Prins)
17-2 Reaction of epoxides with strong bases
17-11 From epoxides or alkenes via selenoxide cleavage
18-3 Ring opening of cycloalkyl carbocations
18-31 Rearrangement of Li salts of 2-vinylcyclopropanols

18-33 Rearrangement of allylic aryl ethers (Claisen)
18-35 [2,3] Sigmatropic rearrangements

Unsaturated Carbonyl Compounds

10-105 Vinylation of ketones or carboxylic esters
10-107 Hydrolysis of bis(methylthio)alkenes
12-2 Isomerization of α-hydroxy alkynes and alkynones
12-14 Acylation of alkenes
12-25 From lithium acetylids
12-30 From vinylic organometallic compounds
12-53 From allylic amines and CO
14-6 Oxidation of unsaturated aldehydes
14-38 Decarboxylative allylation of keto acids
15-19 Nazarov cyclization
15-21 Addition to activated alkynes (Michael)
15-24 Addition of vinylic organometallic compounds to unsaturated carbonyl compounds; addition of organometallic compounds to acetylenic carbonyl compounds
15-25 Addition of unsaturated boranes to methyl vinyl ketones
15-30 Hydrocarboxylation of triple bonds
15-45 Addition of acyl halides to triple bonds
15-46 1,4-Addition of acetals to dienes
16-15 Reaction between aldehydes, ammonia, and aldehydes, ketones, or carboxylic esters (Mannich)
16-30 Addition of conjugated alkenes to aldehydes (the Baylis–Hillman reaction)
16-31 Reaction between aldehydes or ketones, zinc, and α-halo esters (Reformatsky)
16-38 Condensation of aldehydes and/or ketones (aldol)
16-39 Mukaiyama aldol reactions
16-40 Condensation between carboxylic esters and aldehydes or ketones
16-41 Condensation between active-hydrogen compounds and aldehydes or ketones (Knoevenagel)
16-44 Condensation between anhydrides and aldehydes (Perkin)
16-47 Condensation between β-carboxy phosphoranes and aldehydes or ketones
16-48 Tebbe, Petasis, and alternative alkenylations
17-3 Pyrolysis of lactones
17-11 Cleavage of carbonyl-containing selenoxides and sulfones
17-28 Fragmentation of epoxy hydrazones
18-29 Rearrangement of vinylic hydroxycyclopropanes
18-32 Rearrangement of 3-hydroxy-l,5-dienes (oxy-Cope)
18-33 Rearrangement of allylic vinylic ethers (Claisen)
18-35 [2,3] Sigmatropic rearrangements

19-2 Dehydrogenation of aldehydes or ketones
19-14 Oxidation of a methylene group a to a double or triple bond

Unsaturated Ethers and Thioethers

10-107 Alkylation of allylic ethers
17-24 Elimination of X and OR from β-halo acetals
18-35 [2,3] Sigmatropic rearrangement of allylic sulfur ylids

Unsaturated Nitriles, Nitro Compounds, and Sulfonic Acids and Esters

12-31 Cyanation of vinylic organometallic compounds
15-21 Addition to activated alkynes (Michael)
15-24 Addition of organometallic compounds to activated alkynes
15-33 Addition of HCN to alkynes
15-44 Addition of nitryl chloride to triple bonds
16-41 Condensation between active hydrogen compounds and aldehydes or ketones (Knoevenagel)
18-33 Rearrangemenrt of allylic vinylic sulfones and sulfoxides

Ureas and Thioureas

10-59 Exchange of ureas
12-53 Carbonylation of amines
16-16 Addition of amines to isocyanates or isothiocyanates
16-18 Addition of amines to CO_2 or CS_2
16-56 Addition of alcohols or other carbocation sources to cyanamides (Ritter)
18-13 Reaction between amides and lead tetraacetate

Ureides *(see* Imides)

Urethanes *(see* Carbamates)

Vinylic Ethers *(see* Enol Ethers)

Vinylic Halides

10-68 Halide exchange
12-28 Halogenation of alkenyl organometallic compounds
15-2 Addition of hydrogen halides to triple bonds
15-37 Halogenation of alkynes or allenes
15-44 Addition of alkyl halides to triple bonds
15-45 Addition of acyl halides to triple bonds

16-22 Addition of PCl_5 to aldehydes or ketones
16-47 Reaction of halophosphoranes with aldehydes or ketones; reaction of certain ylids with halogen compounds (scoopy reactions)
16-48 Tebbe, Petasis and alternative alkenylations

Xanthates

16-9 Addition of alcohols to carbon disulfide
17-4 Reaction of alcohols with NaOH and CS_2, followed by methyl iodide

Ylids *(see* Nitrogen Ylids, Phosphoranes)

AUTHOR INDEX

Entries in this index refer to chapter number (boldface) and reference number.

SUBJECT INDEX

A nomenclature, IUPAC for mechanisms, 384
A-values, table, 174
α/β nomenclature, for steroids, 146
$A_{AL}1$ mechanism, and ester hydrolysis, 473
$A_{AL}2$ mechanism, and ester hydrolysis, 473
ab initio studies, 34, 36
  1,2 alkyl shifts, electrophilic, 1392
  acids and bases, 339
  and enolate anions, 237
  and nitrenes, 253
  and the Mills-Nixon effect, 690
  and the norbornyl cation, 415
  cubyl cation and the S_N1 reaction, 397
  electrophilic addition to cyclopropanes, 990
  MO, of bromonium ion, 973
  nucleophilic addition to carbonyls, 1173
  S_N2 reaction, 393
  transition state structures for radicals, 900
ab initio, acid strength calculation, 328
Absolute configuration, 138-143
  and diastereomers, 146
  and glyceraldehyde, 138
  and Mosher's derivatives, 142-143
  and radicals substitution, 899
  and the CIP system, 139–141
  and the S_E2 reactions, 761
  and x-ray, 142
  by derivatization, 142-143
  determination of, 141-143
  insertion reactions of carbenes, 790
Absolute hardness, 341
Absorption
  and photochemistry, 308
  differential, and resolution, 152
Abstraction
  of nitrenes, 254
  and radicals, 896
  hydride, photochemical, 1513
  hydrogen, radical, and the Hammett equation, 903
  radical, rate of reaction, 901
Acenaphthylene, reaction with DBr, 975
Acetals
  and enol ether formation, 1181
  and the Mukaiyama aldol reaction, 1223
  by the Prins reaction, 1642
  by transacetalation, 1181
  by transetherification, 480, 1642
  elimination reactions, 1329
  from α-halo ethers, 1642
  from alcohols, 997, 1180, 1642
  from aldehydes, 1180, 1642
  from alkenes, 1642
  from alkoxides, 477, 1642
  from alkynes, 997, 1642
  from cyclization of p-hydroxy ethers, 1642
  from dihalides, 477, 1642
  from Grignard reagents, 1642
  from ortho esters, 1642
  from phenols, 1642
  hydrogenolysis, reagents for, 528
  hydrolysis, 465
  hydrolysis and the Br0nsted coefficient, 466
  hydrolysis and the S_N1 mechanism, 466
  hydrolysis, and microwaves, 467
  hydrolysis, reagents for, 467
  ketene, reaction with aldehydes or ketones, 1249
  ketene, silyl, and the Mukaiyama aldol reaction, 1223
  rate of hydrolysis and structure, 466
  reaction with carboxylic acids, 489
  reaction with Lewis acids, 467
Acetamides, N-chloro, rearrangement of, 728
Acetates
  allylic, coupling with carboxylic acids, 944
  coupling with nickel tetracarbonyl, 545
  elimination with Pd, 1330
  reaction with organocuprates, 545
Acetic acid
  and acid strength, 327
  pK_a, 342

Acetic acid *(Continued)*
reaction with alkenes and $NaNO_2$, 1339
thermodynamic ionization values, 350
Acetic anhydride
and DMSO, for oxidation of alcohols, 1516
cleavage of ethers, 489
dehydrating agent, 491
reaction with alkenes, 1058
reaction with oximes, 1348
Acetic-phosphoric anhydride, acylation of alcohols, 483
Acetoacetic ester
synthesis, 549
enol of, 74-75
Acetoacetic esters
alkylation, 549
dianion, 5S0
Acetolysis, substituent effects, 412
Acetone, as a solvent, 450
Acetonitrile
as a solvent, 450
reaction with hydrocarbons, 925
Acetyl hypofluorite, and aromatic fluorination, 707
Acetyl tosylate, cleavage of ethers, 490
Acetylene, see ethyne
Acetylene
dicarboxy, reaction with bromine, 973
reaction with aromatic compounds, 708
Acetylides, see alkyne anions
Achirality, definition, 125
Aci form
nitronic acids, 76
of nitro compounds, 76
Acid derivatives
reaction with amines, 512
reaction with Grignard reagents, 567
reactivity and leaving groups, 449
Acid form, azinic acids, 76
Acid strength
ab initio calculation, 328
acetic acid, 342
alcohols vs. carboxylic acids, 344
alcohols, order of, 350
amides, 344
amines, 344
and conformation, 347
and diazonium salts coupling, 700
and entropy effect, 347
and equilibrium constants, 336
and free energy, 336
and H_o, 334-335
and hybridization, 348-349
and hydrogen bonding, 99, 101-102, 346
and hydron donors, 352
and inductive effects, 17
and internal hydrogen bonding, 333
and lyonium ions, 335
and principle of imperfect synchronization, 334
and reaction medium, 349-351
and reaction with metals, 793
and solvation, 349
and steric effects, 346
and structure, 342-349
and the Hammett reaction constant, 350
and the Periodic table, 345
C-H, and hybridization, 433
crystallographic scale, 328
definition, 327
esters, 344
ethers, 344
field effects, 342-343
gas phase, 350
Hammet acidity function, 334
hydroxybenzoic acids, 346
kinetic, 228-229
Lewis acids, 340
nitroacetic acid, 342
of 1,3-pentanedione, 347
of β-hydrogen in E2 elimination, 1316
of dimethyl malonate, 347
of dinitromethane, 230
of fluorene, 52
of indene, 52
of Meldrum's acid, 347
of nitromethane, 230
of pentakis(trifluoromethyl)cyclopentadiene, 52
of quinoline conjugate acid, 347
of solvents, 334-336
of squaric acid, 70
phenols, 345
resonance effects, 343-345
scales of acidity, 335
statistical effects, 345-346
t-butylbenzoic acids, 346
table, 329-331
table of acidity constants, 343
the Bunnett-Olsen equation, 335
thermodynamic, 228
tri(pentafluorophenyl)methane, 343
tricyanomethane, 344
triphenylacetic acid, 343
Acid, definition, 333
Acid, formic, see formic acid
Acid, salts, see carboxylic acid salts
Acidity constants, 327-328, 333, 343
Acidity scales, 335

Acids, also see carboxylic acids
Acids
addition to ketenes, 992
and Br0nsted theory, 327-328
and catalysis, 336-338
as proton donors, 327
carboxylic, see carboxylic acids
hard and soft, definition, 340
hardness, table, 340
Lewis, see Lewis acids
mineral, reaction with alcohols, 518
peroxy, see peroxyacids
reaction with alkenes, 991
reaction with alkynes, 975
reaction with cyclopropanes, 989
reaction with organometallic compounds, 794
super acids, 328
thio, see thioacids
Acrolein, reaction with borane, 1031
Acrylonitrile, conjugate addition to, 976
Actinometer, definition, 322
Activated complex, and transition states, 279
Activating groups
and electrophilic aromatic substitution, 681-684
and Friedel-Crafts alkylation, 709
and the Ullmann reaction, 871
electrophilic aromatic substitution, multiple substituents, 687
for S_NAr reactions, 858
chair-to-chair interconversions, 173
Activation hardness, and electrophilic aromatic substitution, 692
Activation volume, and high pressure reactions, 457-458
Activation
free energy of, 278-279
free energy, and reaction coordinate, 279
Active hydrogen compounds
base catalyst condensation, 1219
and the Knoevenagel reaction, 1225-1228
Michael addition to alkenes, 1022-1024
reaction with aldehydes or ketones, 1225-1228
reaction with aryl halides, 869
Acyl anions, and Umpolung, 553
Acyl azides, see azides
from acyl halides, 515
Acyl bromides, from aldehydes, 914
Acyl carbon, and leaving groups, 448
Acyl cations, 223
Acyl cations, see acylium ion
Acyl chlorides, see chlorides, acyl
Acyl cyanides, from acyl halides, 573
Acyl fluorides
from acyl chlorides and HF, 524
from anhydrides and HF, 524
from DAST, 524
Acyl fluoroborates, reaction with alkenes, 1058
Acyl halides, see halides, acyl
Acyl hydrazides, conversion to esters, 488
Acylals, from acylation of aldehydes, 1642
Acylals
from acylation of ketones, 1642
from addition of carboxylic acids to alkynes, 1642
from aldehydes and anhydrides, 1245
from bisdecarboxylation of malonic acids, 1642
from oxidation of arylmethanes with CrO_3 and Ac_2O, 1642
Acylation, 569
Acylation
Friedel-Crafts, 712-714
of alkenes, 784
of amines, 511
of amino acids, 812
of aromatic rings, 710
of conjugated dienes, 784
of enamines, 788
of esters, 569-570
of ketones, 569
reductive, of ketones, 1182
with aldehydes, of heterocycles, 934
Acylhydrazides, reaction with nitrous acid, 1412
Acylium ion, reaction with alkenes, 784
Acyloin condensation, 1562
with tethered diesters, 1602 (ref. 748)
Acyloins, also see hydroxy (a-) ketones
Acyloins, and the benzoin condensation, 1243
Acyloxy amides by the Passerini reaction, 1252
Acyloxylation
of alkenes, 997, 1033, 1048, 1058
of hydrocarbons, 923
of ketones, reagents for, 923
Acylureas, for Hofmann rearrangement, 1411
Adamantanes, 1396
and optical activity, 131
cleavage during hydrogenation, 815
Adamantanones, 1173
Adamantyl cation, 224-225, 1383
Adamantyl compounds, and solvent ionizing power, 452
Addition compounds, 102–114
definition, 102

Addition reactions
of nitrenes, 254
mechanism, 276
of radicals, 246
to cyclopropanes, 988-990
Addition
1,2 vs. 1,4, 980
1,4, see addition, conjugate
alcohols to alkenes, 996
alkenes to alkenes, and Ziegler catalysts, 1020
Addition, conjugate, 979-981
alkyl halides to dienes, 1047
amines to alkenes, 1000
and chiral templates, 1029
and enolate anions, 1023
and Grignard reagents, 1028
and Mannich bases, 1023
and organolithium reagents, 1029
and S_N2' reactions, 980
chiral additives, 1023
cyanoethylation, 976
definition, 976
enantioselectivity of, 1029
hydrogenation of dienes, 1005
Michael addition, 976
organocuprates, 1027
reduction, 1008-1009
with nucleophiles, 1022-1024
with radicals, 1024
Addition, electrophilic, 276
to alkenes, 970-975
to alkenes, diastereoselectivity, 971
to cyclopropanes, 988-990
Addition, Michael, 977, 1022–1024
Addition, nucleophilic, 276
to alkenes, 1000
and conjugation, 1174
and iminium ions, 1178
and steric hindrance, 1174
to alkenes, 975-977
to carbonyls, 1173
Addition, pericyclic, 276
Addition, radical, 276
intramolecnlar, 985
reversibility, 981
to alkenes, 977-979
to alkenes, and cis/trans isomerization, 979
to alkenes, and ESR, 979
to alkenes, and the Felkin-Ahn rule, 981
to alkenes, by silane tethers, 1032
to alkenes, stereoselectivity, 978
to alkenes, steric effects, 985
to conjugated compounds, 1032
to cyclopropanes, 990
to dienes, 978
Addition, termolecular, 972
Addition
to alkenes, and antiaromaticity, 983
to alkenes, and hyperconjugation, 987
to alkenes, and the Cieplak effect, 988
to alkenes, cyclic mechanism, 979
to alkenes, electronic effects, 987
to alkenes, exo/endo diastereoselectivity, 987
to alkenes, field effects, 987
to alkenes, by alkanes, 1017-1019
to alkenes, by boranes, 1012–1016
to alkenes, reactivity of alkenes, 981
to alkenes, regioselectivity, 984
Addition-elimination mechanism, and substitution at vinyl carbon, 428
and transmetallation, 803
metal hydride, 772
and oxidation-reduction, 1509
Additions, IUPAC rules, 383
Adsorption, and catalytic hydrogenation, 1006
A_E nomenclature, IUPAC for mechanisms, 385
Aggregates, and enolate anions, 237
and organolithium reagents, 237
in dialkylamide bases, 348
Aggregation, effect of HMPA, 349
AIBN
and formation of aryl esters, 870
and hydrogenolysis of alcohols, 527
and radical addition of silanes to alkenes, 1039
and radical coupling of dialdehydes, 1561
and radical cyclization to C=N and C=O, 1244
and reaction of aldehydes with ammonia/NBS, 925
and the Barton-McCombie reaction, 527
conpling silanes and lactones, 536
radical initiator, 911, 914
Alanes, vinyl, 1210
Alcohols
and the Oppenauer oxidation, 1199
acylation with acetic-phosphoric anhydride, 483
Addition to alkynes, 997
Alcohols, alkenyl, fragmentation, 1351
Alcohols, alkynyl, dehydration of, 1327
Alcohols, allylic
by Mislow-Evans rearrangement, 1455
coupling with Grignard reagents, 545
from aldehydes and allylsilanes, 1211
from alkene snlfoxides, 1455
from epoxides, 1329
reduction, reagents for, 1009

Alcohols
and acid strength, 344
and Birch reduction, 1010
and Oppenauer oxidation, 1516
and Swern oxidation, 1516
and the Dess-martin periodinane, 1516
and the Koch-Haaf reaction, 564
and the Meerwein-Ponndorf-Verley reduction, 1199
and the Pinner synthesis, 1183
Alcohols
by Payne rearrangement, 1643
by radical oxygenation, 914
by reduction aldehydes or ketones, 1197–1203
by the Baeyer-Villiger reaction, 1644
by the Barbier reaction, 1205
by the Bouveault-Blanc procedure, 1551
by the Cannizzaro reaction, 1200, 1564, 1644
by the Demyanov rearrangement, 1644
by the Tamao-Fleming oxidation, 482
by the Wittig rearrangement, 1421, 1644
by Wagner-Meerwein rearrangement, 1644
Alcohols
conversion to ethers, 479
coupling by MLi-$TiCl_3$, 544
cyclic, oxidative cleavage, 1521
cyclic, transannular etherification, 920
dehydration of, 479, 1326
dehydration, and Zaitsev's rule, 1327
dehydrogenation, 1515
enzymatic oxidation, 1517
epoxy, ring opening, 462
Alcohols
from acetals, 1643
from acid derivatives, 567, 1214, 1551, 1644
from alcohols, 1393, 1643
from aldehydes, 719, 1564, 1643-1644
from aldehydes and organometallics, 1209-1211
from alkaline cleavage of ethers, 1644
• from alkanes, 1533
from alkenes, 914, 974, 993, 1643, 1643, 1644
from alkenes, reagents for, 914
from allylic alcohols, 1643
from allylic silanes, 1643
from allylic silanes to aldehydes, 1644
from amides, 1644
from amines, 494, 1398, 1643
from anhydrides, 1644
from aromatic compounds, 719, 1643
from boradioxolanes, 1422
from boranes, 796, 1422, 1423, 1644
from carboxylic acids, 1549, 1644
from contraction of rings, 1644
from cyclopropanes, 1643
from epoxides, 529, 546, 1643
from esters, 1214, 1551, 1643, 1644
from ethers, 1421, 1643
from expansion of rings, 1644
from Grignard reagents and aldehydes or ketones, 795, 1205-1209, 1644
from hydrolysis of alkyl halides, 1643
from hydrolysis of carboxylic esters, 1643
from hydrolysis of enol acetals, 1643
from hydrolysis of enol ethers, 1643
from hydrolysis of inorganic esters, 1643
from hydrolysis of ortho esters, 1643
from hydrolysis of sulfonic esters, 1643
from hydroperoxides, 1558, 1644
from hydroxyalkylation of aromatic rings, 1643
from hydroxylation at an aliphatic carbon, 1643
from hydroxylation of silanes, 482
from hydroxymethylation of aromatic rings, 1643
from ketones, 719, 1209-1211, 1643-1644
from nitriles, 1644
from organolithium reagents and aldehydes or ketones, 1205-1209, 1644
from organometallic compounds and alcohols, 1643
from organometallic compounds and aldehydes, 1644
from organometallic compounds and epoxides, 1643
from organometallic compounds and ketones, 1644
from organometallic reagents and oxygen, 1643
from ortho esters, 1643
from ozonides, 1644
from peroxides, 1558
from radicals and aldehydes or ketones, 1644
from rearrangement of alcohols, 1644
from rearrangement of alkenes, 1644
from rearrangement of ethers, 1644
from rearrangements of allylic ethers, 1644
from rearrangements of allylic sulfoxides, 1644
from reduction of esters, 1644
from transesterification, 1643
Alcohols
hydrogenation of, 527
hydrogenolysis of, 527
methyl, and the haloform reaction, 813
optically active, by hydroboration, 1014
order of acid strength, 350

Alcohols
oxidation of silanes, 1643
oxidation to aldehydes or ketones, 1514-1517
oxidation to cyclic ethers, 919
oxidation with *Bacillus stearothermophilus*, 1517
oxidation with chromate, mechanism, 1517
oxidation with chromic acid, 1515
oxidation with chromium derivatives, 1537
oxidation with Collins' reagent, 1514
oxidation with Corey's reagent, 1515
oxidation with DMSO-based reagents, 1515-1516
oxidation with Fremy's salt, 1515
oxidation with hypervalent iodine reagents, 1516
oxidation with Jones reagent, 1514
oxidation with nitroxyl radical, 1515
oxidation with oxoammonium salts, 1515
oxidation with permanganate, and ultrasound, 1515
oxidation with pyridinium chlorochromate, 1514
oxidation with pyridinium dichromate, 1514
oxidation with ruthenium tetroxide, 1515
oxidation with TEMPO-NCS, 1515
oxidation with TPAP, 1515
oxidation with zirconocene complexes, 1515
oxidation, and microwaves, 1515
Alcohols
oxidative dehydrogenation with copper chromite, 1515
photochemical addition to alkenes, 997
Alcohols
reaction with acyl halides, 482
reaction with aldehydes or ketones, 1180
reaction with alkenes, 996
reaction with alkyl halides, 564
reaction with amides, 488
reaction with anhydrides, 483
reaction with aryl halides, 870
reaction with carbon disulfide, 1184
reaction with carboxylic acids, 484-486
reaction with chlorotrimethylsilane, 527
reaction with cyanogen chloride, 1183
reaction with DAST, 519
reaction with diazo compounds, 479
reaction with diazomethane, 479
reaction with dihydropyran, 996
reaction with diisopropyl azodicarboxylate, 502
reaction with enol esters, 487
reaction with enol ethers, 487
reaction with esters, 486
reaction with ethers, 480
reaction with Grignard reagents, 526
reaction with HI, 518
reaction with hydrazoic acid, 502
reaction with isocyanates, 1182–1183
reaction with isothiocyanates, 1183
reaction with lactones, 487
reaction with Lawesson's reagent, 496
reaction with lead tetraacetate, 919
reaction with nitriles, 1183
reaction with nitriles, 1244
reaction with nitrous acid, 493
reaction with onium salts, 482
reaction with phosgene, 483
reaction with phosphorus halides, 518
reaction with $POCl_3$, 493
reaction with PPh_3 and CBr_4, 519
reaction with sulfonamides, 576
reaction with sulfonyl chlorides, 576
reaction with sulfur trioxide, 493
reaction with thionyl chloride, 493, 518
reaction with triflic anhydride, 493
reaction with trimethylaluminum, 544
Alcohols
reactivity with alkenes, 996
reagents for hydrogenolysis, 527
vinyl cyclic, and sigmatropic rearrangements, 1440
Alcoholysis
of acyl halides, 482
of amides, 488
of anhydrides, 483
of epoxides, 481
of esters, 486
of lactones, 487
Aldehydes
acylation of, 1245
addition of boranes, 1210
addition to alkenes, 1033
Aldehydes
and Benedict's solution, 917
and Fehling's solution, 917
and Gomberg-Bachmann pinacol synthesis, 1560
and hydroxyalkylation of aromatic rings, 719
and radical cyclization, 1244
and the Barbier reaction, 1205
and the Bouveault-Blanc reaction, 1199
and the Cannizzaro reaction, 1200, 1564
and the Claisen reaction, 1224
and the Darzen's glycidic ester condensation, 1230

and the Eschweiler-Clarke reaction, 1188
and the Fischer indole synthesis, 1453
and the Knoevenagel reaction, 1225–1228
and the Leuckart reaction, 1188
and the Meerwein-Ponndorf-Verley reduction, 1199
and the Passerini reaction, 1252
and the Paterno-Bchi reaction, 1249
and the Perkin reaction, 1229
and the Sonn-Mller method, 534
and the Wallach reaction, 1188
Aldehydes, aromatic
and the Duff reaction, 717
and the Tishchenko reaction, 1565
by bromination of methyl aryls, 1534
by the Étard reaction, 1534
by the Gatterman reaction, 715
by the Gatterman-Koch reaction, 715
by the Reimer-Tiemann reaction, 716
by the Vilsmeier reaction, 715
decarbonylation, 732
from aromatic compounds, 715
from methyl aryls, 1533
oxidation of, 1528
reaction with $Al(OEt)_3$, 1565
reaction with sulfuric acid, 732
Aldehydes
by Hofmann rearrangement, 1645
by hydrolysis of imines, 552
by McFadyen-Stevens reduction, 534
by Oppenauer oxidation, 1516
by pinacol rearrangement, 1645
by reduction of amides, 1550
by Stephen reduction, 1204
by Swern oxidation, 1516
by the Barton reaction, 1463, 645
by the Dess-martin periodinane, 1516
by the Étard reaction, 1646
by the Gatterman reaction, 1645
by the Kröhnke reaction, 1536
by the Meyers synthesis, 558
by the Nef reaction, 1178, 1645
by the Oppenauer oxidation, 1199
by the oxo process, 1645
by the Pummerer rearrangement, 1566
by the Reimer-Tiemann reaction, 1645
by the Rosenmund reduction, 532
by the Sommelet reaction, 1536
by the Sonn-Müller method, 1204
by the Vilsmeier reaction, 1645
by the Wacker process, 1538
Aldehydes, chiral, in the aldol reaction, 1222
Aldehydes, conjugated
and Michael reactions, 1022-1024
and the Grignard reaction, 1205
by [2,3] sigmatropic rearrangement, 1454
reaction with borane, 1031
reaction with organocuprates, 1027
Aldehydes
conversion to amides, 925
decarbonylation, 944
decarbonylation and radical rearrangement, 1389
dissolving metal reductions, 1199–1200
enolate anion of, also see enolate anions
Aldehydes

from rearrangement of aryl hydroxylamines, 1654
from rearrangement of arylamines, 1654
from rearrangement of benzidines, 1655

Amines *(Continued)*
from rearrangement of benzylic ammonium salts, 1654
from rearrangement of hydroxamic acids, 1655
from rearrangement of **N-haloamines,** 1655
from rearrangement of N-nitroamines, 1654
from rearrangement of N-nitrosoamines, 1654
from rearrangement of triazenes, 1654
from rearrangement of ammonium salts, 1655
from thioamides, 1654
from transamination, 1654
Amines
halo, reagents for their preparation, 819
methyl, from isothiocyanates, 1555
methylation with diazomethane, 504
N,N-dichloro, **rearrangement** of, 1410
N-arylation of, **501**
N-chloro, reaction with $AgNO_3$ in methanol, 1416
N-chloro, reaction with **alkenes,** 1045
N-halo, and the Stieglitz rearrangement, 1417
N-iodo, photolysis of, 1463
N-methyl, from reduction of **isonitriles,** 1204
order of base strength, 349
oxidation of, 1535-1536, 1539
oxidation with hydrogen peroxide, **1141**
oxidation with peroxides, **1541**
oxidation with **peroxyacids,** 1541
protection of, 577, 697
Amines
reaction with acids derivatives, **512**
reaction with aldehydes or **ketones, 1185–1187**
reaction with alkenes, 999, 1056
reaction with alkoxyphosphonium perchlorates, 502
reaction with alkynes, 1000
reaction with amide bases, 503
reaction with amides, 503
reaction with **aryl** halides, 864
reaction with azides, 781
reaction with aziridines, 505
reaction with chloroform, 506
reaction with **chloroformates,** 507
reaction with CO, 820
reaction with CO_2, 820, **1192**
reaction with CS_2, **1192**
reaction with cyanogen bromide, 522
reaction with diazo compounds, 504
reaction with diazoalkanes, 1217
reaction with diynes, 1000
reaction with esters, **510**
reaction with **hydroxylamine-O-sulfonic** acid, 530
reaction with **hypobromites,** 819
reaction with hypochlorites, 819
reaction with hypohalites, 819
reaction with isocyanates, **1191**
reaction with isocyanic acid, **1191**
reaction with isopropenyl formate, **511**
reaction with isothiocyanates, **1191**
reaction with **ketenimines,** 1001
reaction with ketones, 552
reaction with $KMnO_4$, 1539
reaction with KNO_2, 494
reaction with **N-chloromethyl** lactams, 500
reaction with **NaOCl,** 1518
reaction with NCS, 500
reaction with nitric acid-acetic anhydride, **818**
reaction with nitrous acid, 816-817, 1398
reaction with **NOCl, 818**
reaction with organocuprates, 800
reaction with organolithium reagents, 500
reaction with oxetanes, 505
reaction with Oxone, 1540
reaction with phenol and **formaldehyde,** 722
reaction with phosgene, 507
reaction with pyrylium ions, **1186**
reaction with sulfonyl chlorides, 576-577
Amines
reduction by **Katritzky** pyrylium-pyridinium method, 530
reductive alkylation, **1188**
test for primary amines, 506
Aminium radical cations, 909
Aminium radical ion, 701
Amino acids
acylation of, 812
and the Dakin-West reaction, 812
aryl, preparation of, 720
by the **Hofmann** reaction, 1656
by the Sorensen reaction, 549, 1656
by the Strecker synthesis, **1656**

coupling with allylic acetates, 944
decarboxylation of, 808
dehydration of, 491
dianions, 555
dianions, reaction with esters, 572
esterification of, 484-486
Carboxylic acids
from 1,1-dichloroethene, 1661

from acyl halides, 1405
from alcohols, 1537
from aldehydes, 917, 1229
from aldehydes and base, 1662
fromalkenes, 1035-1036, 1661
from alkyl halides, 564, 1661
from alkynes, 1523, 1539, 1540
from anhydrides, 1229
from aromatic compounds, 1527, 1661
from aryl halides, 1661
fromboranes, 1424, 1661
from carbon dioxide, 1215, 1661
from carboxylate ions, 1661
from cleavage of P-diketones, 1661
from cleavage of p-keto esters, 1661
from cleavage of carboxylic esters, 1661
from cleavage of ketones. 1661
from cleavage of nonenolizable ketones, 1661
from cleavage of secondary alcohols, 1661
from CO, 1661
from decarboxylation of dicarboxylic acids, 1661
from diazoketones, 1405
from diazonium fluoroborates, 1661
from enolate dianions, 1424
from esters, 549
from fragmentation of certain oximes, 1661
from Grignard reagents, 1215, 1661
from halo ketones, 1403
from hydrocarbons, 564
from hydrolysis of 1,1,1-trihalides, 1660
from hydrolysis of acyl halides, 1660
from hydrolysis of amides, 1661
from hydrolysis of anhydrides, 1661
from hydrolysis of carboxylic esters, 1661
from hydrolysis of nitriles, 1661
from hydrolysis of ortho esters, 1660
from hydrolysis of oxazines, 1661
from hydrolysis of primary nitro compounds, 1661
fromketenes, 1661
from methyl ketones, 813
from nitriles, 1179
from oxazolines, 559
from oxidation of 1,1-diboranes, 1661
from oxidation of aldehydes, 1661
from oxidation of amines, 1662
from oxidation of aromatic side chains, 1662
from oxidation of aryl ketones, 1662
from oxidation of arylthioalkynes, 1662
from oxidation of ethers, 1662
from oxidation of ozonides, 1661
from oxidation of primary alcohols, 1662
from oxidative cleavage of α-diketones, 1661
from oxidative cleavage of α-keto acids, 1661
from oxidative cleavage of alkenes, 1525–1526, 1661
from oxidative cleavage of aromatic rings, 1661
from oxidative cleavage of terminal alkynes, 1661
from ozonolysis of alkenes, 1522
from ozonolysis of alkynes, 1661
from Petasis alkenylation, 1661
from phosphoranes, 1661
from pyrolysis of carboxylic esters, 1661
from pyrolysis of esters, 1329
from rearrangement of α-halo ketones, 1661
from rearrangement of aromatic carboxylate ions, 1661
from rearrangement of aromatic nitro compounds, 1661
from rearrangement of diazo ketones, 1661
from reductive cleavage of carboxylic esters, 1661
from Tebbe alkenylation, 1661
from the haloform reaction, 1661
from unsaturated carboxylic acids, 1661
Carboxylic acids
gas phase acidity, 350
methylation with Me_3Al, 1214
monoesters, 483, 487
oxidation with peroxides, 1542
oxidative decarboxylation, 1528
pyrolysis with ThO_2, 573
Carboxylic acids
reaction with acyl halides, 523
reaction with alcohols, 484-486
reaction with alkenes, 997
reaction with alkynes, 998
reaction with ammonia, 508
reaction with boranes, 1005
reaction with bromine, 777
reaction with carbonyls and isonitriles, 1251
reaction with copper, 732
reaction with diazo compound, 490
reaction with diazomethane, 490
reaction with dimethylformamide acetals, 489
reaction with enol esters, 491
reaction with esters, 491
reaction with ethers, 486
reaction with heterocycles, 933
reaction with hydrazoic acid, 1413
reaction with LDA, 555
reaction with lead tetraacetate and cupric acetate, 1528
reaction with NBS or NCS, 778

Carboxylic acids *(Continued)*
reaction with organolithium reagents, 568
reaction with oxalyl chloride, 523
reaction with P_4S_{10} and alcohols, 1184
reaction with pyridine, 933
reaction with quinolines, 933
reaction with thionyl chloride, 523
reaction with vinyl boranes, 1005
Carboxylic acids
reduction with borane, 1549
reduction with Li and amines, 532
reduction with $LiAlH_4$, 1549
selective reduction, 533
table of pK_as, 343
thermolysis of, 1327

Demethylation
of ethers, 496, 503, 520, 528
of methyl esters, 562
of methypyridinium salts, 501
Demyanov rearrangement, 1399
Demyanov ring contraction or expansion, 1398-1400
Dendralenes, 39, 80
Deoxygenation, of aryl ethers, 734
Deracemization, and resolution, 154
Derivatization
and absolute configuration, 142–143
and Mosher's acid, 142-143
Dess-Martin periodinane, and oxidation of alcohols, 1516

Desulfurization, 531
by **hydrogenation,** 940
of **thiophene,** 941
Deuteration
of aromatic rings, reagents for, 696
of hydrocarbons, 769
exo-**Deuterio**-*exo*-**norbornyl** acetate, 1442
Deuterium exchange, and electrophilic aromatic substitution, 695
Deuterium isotope effects, 298
Deuterium, catalytic exchange with alkanes, 1005
Deuterium, effect on nucleophilic substitution, 438
Dewar benzene, 1083, 1090, 1449
Dewar benzenes, by **electrocyclic** rearrangement, 1433
Dewar structure, anthracene, 43
Dewar structures, 32
Dextro **isomers,** and chirality, 125
DHU, see **dicyclohexylurea**
Di-alkynes, see diynes
Di-π- methane rearrangement, 1460
Di-π- methane rearrangements, oxa, 1461
Di-*sec*-butylmercury, reaction with **Grignard** reagents, 761
Dialdehydes
cyclization with rhodium phosphine complex, 1564
radical cyclization, 1561
Dialkylboron **enol** ether, see **enol** borinate
Diamantane, 1396
1,2-Diamines, from **dimerization** of iraines, **1561**
Diamines
cyclic, and the anomeric effect, 177
from **alkenes,** 1056
from aziridines, 504, 505
ortho-, oxidation with nickel peroxide, 1527
oxidative cleavage, 1520
1,4'-Diaminobiphenyl, 1456
Diaminobiphenyls
from hydrazobenzenes, 1455
by the benzidine rearrangement, 1455
Dianions
carboxylic acid, reaction with esters, 572
from ketones and CS_2, **1229**
from the acyloin condensation, 1562
of acetoacetic ester, 550
of carboxylic acids, reaction with **alkyl** halides, 555
Diaryl **sulfides,** see thioethers, **aryl**
2,3-Diarylthiiren-1,1-dioxides, 1343
Diarylhydrazines, see hydrazo compounds
Diaryls, see biaryls
Diasterane, **183**
Diastereomer, definition, 144
Diastereomers
and cis/trans isomers, **157–160**
and diastereotopic atoms, 164-166
and **epimers,** 146
and **isomer** formation in elimination reactions, 1318
and Michael addition, 977
and pseudo asymmetric carbons, 145
and resolution, **151–152**
and substitution reactions, 405
and the 2° rale, 145
differences in reactivity, 366
erythro, from electrophilic addition to alkenes, 971
erythro/threo nomenclature, 146-147
meso compounds, 145
nomenclature, 146
physical properties, 144
syn/anti nomenclature, 147
threo, from electrophilic addition to alkenes, 971
torsional, 133
Diastereoselectivity
and Cram's rale, 147-148
and the **Felkin-Ahn** model, 148
and the **Paterno-Büchi** reaction, 1250
electrophilic addition to alkenes, **971**
erythro/threo, in the **aldol** reaction, **1221**
exo/endo, and addition to alkenes, 987
in addition to aldehydes or ketones, 1206
in conjugate additions, 1029
in Mannich reactions, **1191**
in reduction of aldehydes and ketones, 1201
in the aldol reaction, **1221**
in the Knoevenagel reaction, 1225
in the Prins reaction, 1242
in the Reformatsky reaction, **1212**
syn/anti, in the aldol reaction, **1221**
Diastereotopic atoms, 164-166
and isochronous atoms, 165
Diastereotopic faces, 166
Diastereotopic, definition, 165
Diatopic compounds, definition, 46
1,4-Diazabicyclo[2.2.2]octane, see DABCO
1,5-Diazabicyclo[3.4.0]non-5-ene, see DBN
1,8-Diazabicyclo[5.4.0]undecene, see DBU
Diazirines, decomposition of, 250
Diazo alkanes, from nitroso compounds, 1352
Diazo compounds
from **α-amino** esters, 1664
from active hydrogen compounds, 1664
from **acyl** halides, 1664

from aldehydes, 1664
from aliphatic amines, 816
from amines, 816
from diazo esters, 1664
from hydrazones, 1664
from N-nitroso-N-alkyl compounds, 1664
photooxidation and ozonolysis, 1524
protonation, 447
reaction with alcohols, 479
reaction with amines, 504
reaction with boranes, 561
reaction with carboxylic acids, 490
reaction with phenols, 479
Diazo esters
reaction with aldehydes, 785
reaction with boranes, 561
Diazo ketones
and ketene formation, 1250
and the Arndt-Eistert synthesis, 1405
and Wolff rearrangement, 1406
conformations of, 1407
hydrolysis of, 465
intermediates in the Schmidt reaction, 1414
photolysis of with alcohols, 1406
reaction with HBr, 522
rearrangement of, 1414
rearrangement with water and Ag_2O, 1405
s-(E) and *s*-(Z) conformations, 1407
thermolysis of, 1250
Diazo transfer reaction, 781
Diazoalkanes
as 1,3-dipoles, 1060
reaction with aldehydes or ketones, 1248
reaction with imines, 1217
reaction with sulfur, 1248
reaction with thioketones, 1248
Diazoketones
by the Arndt-Eistert synthesis, 574
from acyl halides, 573
reaction with boranes, 561
Diazomethane
and carbenes, 248, 249
and homologation of aldehydes and ketones, 1407
conversion to methylene carbene, 789
decomposition of, 250
photolysis of, 789
rate of decomposition, 1087
reaction with acyl halides, 573, 1405
reaction with alcohols, 479
reaction with aldehydes or ketones, 1248
reaction with amines, 504
reaction with carboxylic acids, 490
reaction with sulfonyl halides, 1249
Diazonium compounds
aryl, 816
by diazo transfer reactions, 781
from active methylene compounds, 780
stability of, 816
Diazonium coupling, 700
Diazonium ions, 448, 700
and amide hydrolysis, 475
and the Bamford-Stevens reaction, 1335
ionization to carbocation, 1393
Diazonium salts, 448
and ionization to aryl cations, 853
aryl, and isomerization, 700
aryl, coupling, 700
aryl, coupling and acidity, 700
aryl, coupling with alkenes, 929-930
aryl, coupling with arylboronic acids, 938
aryl, formation of, 701
aryl, mechanism of formation, 817
aryl, methylation of, 937
aryl, reaction with aromatic compounds, 928
aryl, reaction with CuCl or CuBr, 935-936
aryl, reaction with CuCN, 936
aryl, reaction with cuprous halides, 935
aryl, reaction with hydrogen sulfide anion, 874
aryl, reaction with hypophosphorous acid, 934
aryl, reaction with iodide, 875
aryl, reaction with Me_4Sn, 937
aryl, reaction with $NaNO_2$, 936
aryl, reaction with oximes, 938
aryl, reaction with SO_2, 937
aryl, reaction with sulfur nucleophiles, 874
aryl, reaction with thiol anions, 874
aryl, reaction with water, 874
aryl, reduction of, 934
coupling with alkenes, 937
from amines, 1664
from aromatic compounds, 1664
reaction with active methylene compounds, 778
reaction with enolate anions, 778
reaction with malonic esters, 779
reduction with $LiAlH_4$, 1556
reduction with sodium sultite, 1556
Diazonium tetrafluoroborates, aryl, thermolysis, 875
Diazonium, as a leaving group, 447
Diazosulfides, as intermediates, 874
Diazotization
of amines, 448, 816
of amino acids, 522

Dibal
reduction of **alkynes,** 1007
reduction of carbonyl compounds, **1198**
reduction of **oximes,** 1555
Dibal/$NiCl_2$-dppp, reduction of **allyl** amines, 1559
Dibromides
from **alkenes,** 1041
from hydrazones, **1196**
1,2-Dibromoethane, dipole moment, 16

and enolate anions, 553
in the aldol reaction, 1220
Vinyltin, reaction with vinyl triflates, 931
Volume of activation, and high pressure reactions, 457-458

Von Braun reaction, 522, **1350**
mechanism of, 523
Von Richter reaction, 289
Von Richter rearrangement, 876

Wacker process, 1538
and Markovnikov's rule, 1538
Wadsworth-Emmons reaction, 1233
Wagner-Meerwein rearrangements, **1384,** 1393-1396
and adamantanes, **1396**
and Lewis acids, 1394, **1396**
and **Nametkin** rearrangements, **1395**
and **norbornyl** cations, **1394**
and retro pinacol rearrangements, **1395**
and **stabilomers, 1396**
and the Stieglitz rearrangement, 1416
and Zaitsev's rule, 1393, 1394
hydride ion migration, 1394
in terpenes, **1394**
Walden inversion, 290, **391**
Wallach reaction, **1188**
Wallach rearrangement, 1464
photochemical, 1465
Water
addition to alkenes, 993
as a solvent for **Diels-Alder** reactions, 1066
reaction with aldehydes or ketones, **1175**
reaction with alkynes, 995
reaction with **aryl** diazonium salts, 874
reaction with isonitriles, **1251**
Wave functions, 3
Westheimer method, 178, **211**
Wheland intermediates, and the I effect, 682-683
Whitmore 1,2 shift, 1378
Wigner **spin-conservation** rule, **316**
Wilkinson's catalyst
and decarbonylation of aldehydes, 944
and **hydroboration,** 1016
and hydrogenation, 1003
Willgerodt reaction, 1567
and the Claisen rearrangement, 1568
and the **Kindler** modification, **1567**
Williamson ether synthesis, 477
Williamson reaction, 477
Wittig reaction, 185, 1213, 1219, 1231-1237
and betaines, 1234
and epoxides, 504
and oxaphosphetanes, 1234
and **scoopy** reactions, 1236
and [2+2]-cycloaddition of **ylid** and **carbonyl,** 1235
E/Z isomers, 1235
in synthesis, 1236
intramolecular, 1236
NMR and intermediates, **1234**
on silica gel, 1233
polymer supported, 1233
salt effects, **1235**
salt-free, 1232
silyl, 1228
stereoselectivity, 1235
structural variations in the ylid, 1232
Wittig **rearrangement,** 558, 1421, 1454
aza-, 1422
migratory aptitudes, **1421**
Wittig-Horner reaction, 1233
Wohl-Ziegler bromination, 911
Wöhler, synthesis of **urea, 1191**
Wolff rearrangement, 1250, 1405
and carbenes, 252
and the **Arndt-Eistert** synthesis, 1405
photochemical, 1406
Wolff-Kishner reduction, 1547
Woodward-Hoffmann rules, 1068, **1083, 1091,** 1092
and pyrolytic elimination, 1324
Wurtz reaction, 535
acyl halides and lead, 568
and dihalides, 536
and formation of **organolithium** reagents, 806
and Grignard reagents, 1207
and SmI_2, 536
and the Ullmann reaction, **871**
in reactions of organometallics and **alkyl** halides, 807
intramolecular, 536
preparation of strained molecules, 536
reagents for, 535
Wurtz-Fittig reaction, 535

X-ray diffraction, and bond distance, 18
X-ray, and absolute configuration, 142
Xanthate esters, see esters, xanthate
Xanthates
from alcohols, 1184, 1693
from carbon disulfide, **1184, 1693**
Xenon **difluoride,** and aromatic fluorination, 707
Xray
and **carbenes,** 251
and enolate anions, 236
and intermediates for the Reformatsky reaction, 1213
and lithium **diisopropylamide,** 348
diffraction, of Grignard reagents, 235
of organolithium reagents, 236

photoelectron spectroscopy, see ESCA
Xylene (*m*-), acetylation, isomer distribntion, 691

Y values, and solvent effects, 452—453
Ylids
from alkyl phosphonothionates, 1234
and carbanions, 231
azomethine, as 1,3-dipoles, 1060
bonding, 45-46
from phosphine oxides, 1234
from phosphoric acid bisamides, 1234
keto, pyrolysis of, 1334
nitrile, as 1,3-dipoles, 1060
nitrogen, and field effects, 231
nitrogen, and [2,3]- sigmatropic rearrangement, 1454
nitrogen, from ammonium salts, 792
on silica gel, 1233
phosphonate, 1234
Ylids, phosphorus
and the Wittig reaction, 1231-1237
from phosphonium salts, 793
reaction with anhydrides, 1237
reaction with CO_2, 1237
reaction with imides, 1237
reaction with imines, 1237
reaction with isocyanates, 1237
reaction with ketenes, 1237
reaction with nitroso compounds, 1237
resonance stabilized, 1232
structural variations, 1232
Ylids
polymer supported, 509, 1233
salt-free, 1232
Ylids, sulfur
and Stevens rearrangement, 1420
chiral, 1247
polymer anchored, 1247
reaction with aldehydes or ketones, 1247
reaction with aromatic nitro compounds, 872
reaction with thioketones, 1248
solvent free reactions, 1247
Ylids, thiocarbonyl, as 1,3-dipoles, 1061

Z nomenclature, 157
Zaitsev elimination, with 2-bromopentane, 1318
Zaitsev's rule
and dehydration of alcohols, 1327
and El elimination, 1308
and E2 elimination, 1303
and E2C elimination, 1314
and elimination of alkyl halides, 1337
and elimination of boranes, 1339
and Hofmann elimination, 1331
and pyrolytic elimination, 1325
and regiochemistry in elimination reactions, 1314
and Wagner-Meerwein rearrangements, 1393
definition, 1314
Zeolites
and aromatic substitution, 705
and Diels-Alder reactions, 1066
and Friedel-Crafts acylation, 712
and hydride rednction of aldehydes or ketones, 1197
and the Knoevenagel reaction, 1226
Ziegler alkylation, 871
Ziegler catalysts, 1020
Zinc and acid, reduction of sulfonyl halides, 1556
Zinc chloride
and the Fisher indole synthesis, 1452
in the aldol reaction, 1221
reaction with enolate anions, 1221
Zinc cyanide
reaction with aromatic compounds, 715
reaction with aryl triflates, 724
Zinc metal
and elimination of dihalides, 1343
and HC1, reduction of nitro compounds, 1552
and NaOH, reduction of nitro compounds, 1564
in AcOH, reduction of nitro compounds, 1558
in the Reformatsky reaction, 1212
reaction with sulfonyl chlorides, 577
reduction of aromatic nitro compounds in water, 1554
reduction of hydroxylamines, 1554
reduction of nitroso compounds, 1554
Zinc-copper couple, and the Simmons-Smith reaction, 1088
Zinin rednction, 1552
Zip reaction, and lactams, 512
Zirconocene complexes, oxidation of alcohols, 1515
zusammen nomenclature, 157
Zwitterions
and elimination of hydroxy acids, 1346
and oxime formation, 1194
